## الإهداء

الى كل مسلم يسعى لرقي امته. أهدي هذا العمل المتواضع إلى أبي الذي لم يدخل على يوماً بشيء وإلى أمي التي زودتني بالحنان والمحبة أقول لهم: أنتم وهبتمني الحياة والأمل والنشأة على شغف الاطلاع والمعرفة وإلى إخوتي وأسرتي جميعاً ثم إلى كل من علمني حرفأً أصبح سناً برقه يضيء الطريق أمامي. إلى من علمني النجاح والصبر إلى من افقده في مواجهة الصعاب ولم تمهله الدنيا لأرتوي من حنانه.. أبي وإلى من تتساقب الكلمات لتخرج معبرة عن مكنون ذاتها.

## ACKNOWLEDGEMENT

As always, I give my praise and thanks to the almighty Allah for giving us the strength and health and providing me with his protection and mercy. I would like to thank my family and my friends who inspired me to work hard during the SDP and to chase my dreams, which I believe are almost a reality.

I would also like to thank the project supervisor, Dr. Omar Alawad for his unwavering support, guidance, and expertise throughout the project. We are grateful for the time he spent reviewing our progress, providing feedback, and challenging us to think critically and creatively.

I would also like to thank my fellow students at Qassim University, who provided me with valuable feedback, support, and motivation throughout the project. Their insights and perspectives helped me to refine my ideas and approaches, and their collaboration and teamwork were essential to the success of the project.

Overall, my special heartfelt thanks go to everybody who have supported me during our SDP, as well as those individuals who give special support.

## المُلخص

يركز مشروع التخرج هذا على تحليل وتصميم مبنى إنشائي مسلح، حيث يتم تحديد الأحمال على المبنى وفقاً ل קוד البناء السعودي. يهدف المشروع إلى تصميم مبنى آمن واقتصادي باستخدام برنامج ETABS، يليه التحقق باستخدام Excel، وأخيراً رسم تخطيطات وتسلیح المبنى باستخدام برنامج REVIT.

في المرحلة الأولى، يتم تحديد الأحمال على المبنى من خلال الالتزام باللوائح المحددة في كود البناء السعودي. يحدد الكود الأحمال التي يجب أن يتحملها المبنى، مثل الأحمال المئوية والأحمال الحية وأحمال الرياح والزلزال، ثم يتمأخذ الأحمال في الاعتبار في مرحلة التصميم.

في مرحلة التصميم، يتم استخدام برنامج ETABS لتصميم المبنى. البرنامج قادر على محاكاة أنواع مختلفة من سيناريوهات التحميل لتحديد الاستقرار الهيكلي والقدرة للمبنى. يتضمن التصميم اختيار المواد وأبعاد عناصر البناء وتفاصيل التسلیح.

في مرحلة التتحقق، يتم فحص التصميم باستخدام Excel. تم تصميم ورقة Excel للتحقق من حسابات التصميم والتأكد من أن التصميم يفي بالمتطلبات واللوائح المحددة في كود البناء السعودي.

أخيراً، يتم رسم مخططات تسلیح المبنى باستخدام برنامج REVIT. يسمح هذا البرنامج بإنشاء نموذج ثلاثي الأبعاد للمبنى يمكن استخدامه لتصور التصميم وتحديد أي مشكلات محتملة قبل بدء البناء.

## **ABSTRACT**

This senior design project focuses on the analysis and design of a reinforced structural building, in which the loads on the building are defined according to the Saudi Building Code. The project aims to design a safe and cost-effective building using ETABS software, followed by verification using Excel, and finally drawing the building layouts and reinforcement using REVIT software.

In the first phase, the loads on the building are defined by adhering to the regulations specified in the Saudi Building Code. The code specifies the loads that the building must withstand, such as dead loads, live loads, and wind loads. The loads are then considered in the design phase.

In the design phase, ETABS software is used to design the building. The software is capable of simulating different types of loading scenarios to determine the structural stability and strength of the building. The design includes the selection of materials, dimensions of the building elements, and reinforcement details.

In the verification phase, the design is checked using Excel. The Excel sheet is designed to verify the design calculations, including the dimensions of the building elements, and ensure that the design meets the requirements and regulations specified in the Saudi Building Code.

Finally, the building layouts of the reinforcement are drawn using REVIT software. This software allows for the creation of a 3D model of the building that can be used to visualize the design and identify any potential issues before construction begins.

### ***List of Symbols***

Symbol	Description	Unit
$A_s$	the minimum area of steel required for the member	$m^2$
b	width of the member	m
d	the effective depth of the member	m
$f_c$	Concrete compressive strength	Mpa
$f_y$	Steel tensile strength	Mpa

$a$	The height of the stress block	m
$\Phi$	Reduction factor	unitless
$A_f$	Area of the foundation	$m^2$
$Q_{\text{working}}$	The load of the column	kN
$q_{\text{all net}}$	The net allowable gross soil bearing capacity	$kN/m^2$
$q_{\text{all}}$	Soil bearing capacity	$kN/m^2$
$\gamma_s$	Soil unit weight	$kN/m^3$
$D_f$	Distance from the surface to the top of footing	m
$\gamma_c$	Unit weight of concrete	$kN/m^3$
$t_f$	footing thickness	m
$q_s$	The Contact Soil Bearing Capacity	$kN/m^2$
$Q_{\text{ult}}$	The ultimate load of the column	kN
$V_u$	shear force due to factored load	kN
$\Phi V_c$	design shear strength of concrete	kN
$L_f$	Length of the footing	m
$B_f$	Breadth of the footing	m
$b_c$	Width of the column	m
$h_c$	Height of the column	m
$d_b$	Diameter of the rebar	m
$A_{\text{bar}}$	Area of the rebar	$m^2$
$A_v$	Area of shear reinforcement within spacing s	$mm^2$
$A_{v,min}$	Minimum area of shear reinforcement within spacing s	$mm^2$
$V_c$	Nominal shear strength provided by concrete	KN
$s$	Center to center spacing of items	mm

## **CHAPTER 1. INTRODUCTION**

The design and construction of reinforced concrete buildings is a complex and critical process that requires a thorough understanding of structural analysis, load calculations, and material selection. The purpose of this senior design project is to explore the various aspects of reinforced concrete design and construction, with a focus on ensuring safety, durability, and sustainability. Through our project, we will examine the theoretical and practical considerations for designing a reinforced concrete building, including the application of relevant codes and standards, the use of appropriate software tools for structural analysis, and the selection of materials based on their properties and performance. Our goal is to provide a comprehensive overview of the analysis and design of a reinforced concrete building, with a view toward creating structures that are safe and durable.

## **1.1. Motivation**

Reinforced concrete is a versatile and durable construction material that is widely used in building structures such as bridges, high-rise buildings, and residential homes. The analysis and design of a reinforced concrete building are critical to ensure that the structure is safe, reliable, and meets all applicable building codes and regulations.

The importance of proper analysis and design of reinforced concrete buildings cannot be overstated, as a poorly designed or constructed structure can have devastating consequences. In addition to posing a significant risk to the safety of occupants, a building failure can also result in significant economic losses and damage to communities.

## **1.2. Literature survey**

Reinforced concrete structures have been a subject of extensive research and interest among scholars and practitioners for many years. Researchers have explored various aspects of reinforced concrete design, including material properties, structural behavior, and design codes.

For this project, a comprehensive review of the literature on reinforced concrete design was conducted, with a focus on two prominent design codes: the Saudi Building Code (SBC) and the American Concrete Institute (ACI) Building Code. These codes are widely recognized and used in the industry, providing guidance and standards on the design of reinforced concrete structures, including critical structural components such as beams, columns, and slabs.

## **1.3. Problem definition**

### ***1.3.1. Problem statement***

Develop an efficient and safe design process that incorporates the latest best practices and standards for reinforced concrete buildings. The project aims to address existing design limitations and challenges to ensure the durability and sustainability of the reinforced concrete building.

### ***1.3.2. Problem constraints***

The project is constrained by budget limitations and the need to comply with relevant safety codes and regulations. Additionally, the design must meet the specific functional requirements of the building and the needs of its occupants.

### ***1.3.3. Proposed solutions***

The project's proposed solution involves analyzing and designing the reinforced concrete building using either a flat slab or solid slab system, depending on which is the most economical option for the specific needs of the building and its occupants. The chosen system will be optimized for cost-effectiveness, durability, and compliance with relevant safety codes and regulations.

## **1.4. Design requirements**

When analyzing and designing a reinforced concrete building, there are several design requirements that should be considered. These include:

- Strength and stability: The building must be designed to withstand the expected loads and forces that it will experience during its service life.
- Durability: Building must resist environmental factors for safety.
- Serviceability: Design to meet functional requirements for user comfort.

- Code compliance: Compliance with codes ensures safe building design.

### 1.5. Project Description

An office building architectural plane of 7 floors with three different layouts, at which one of them will be repeated 3 more times. Figures 1-1, 1-2, 1-3 and 1-4 show the architectural plan for each story.

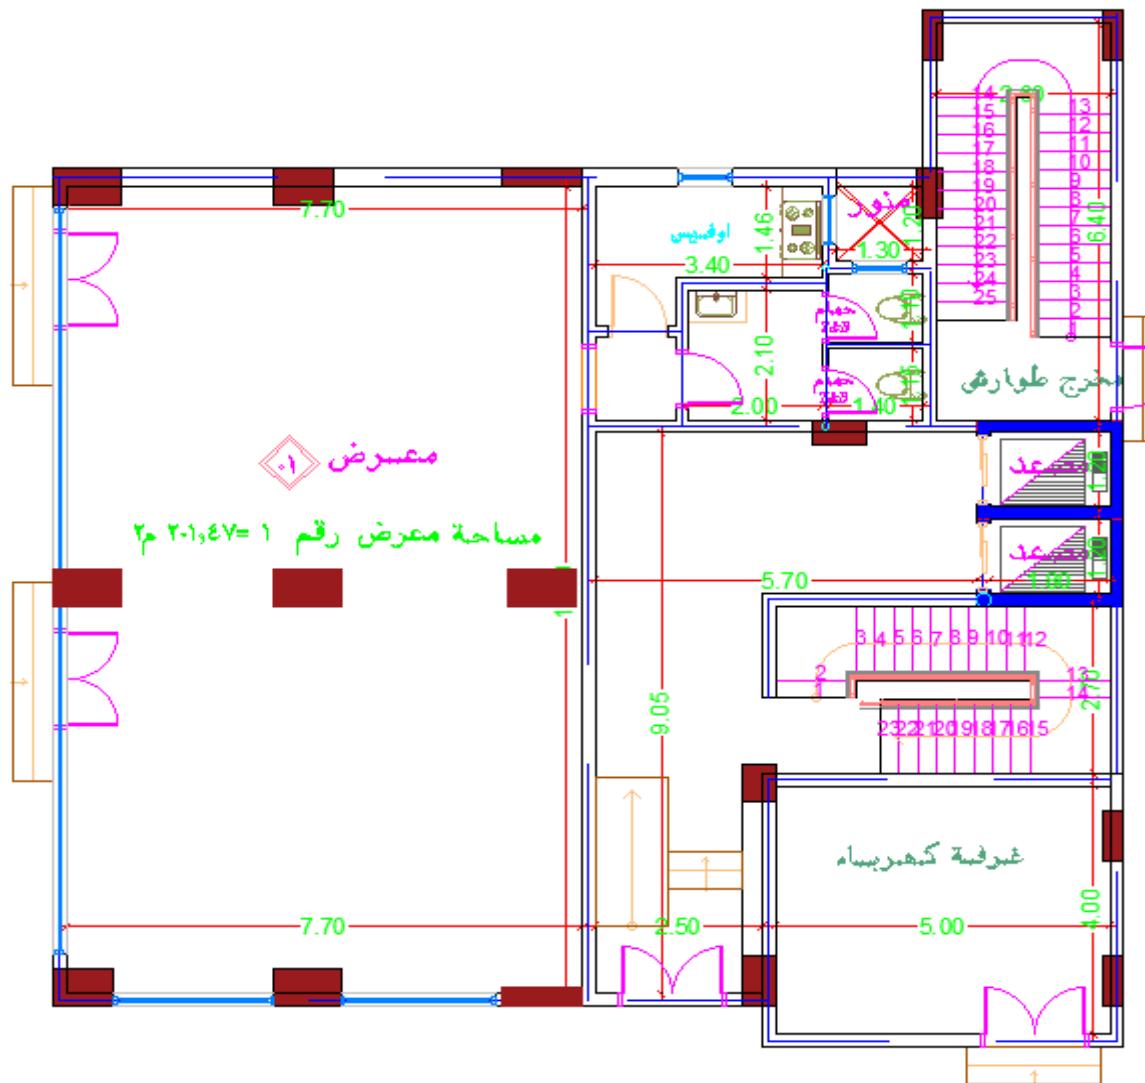

Figure 1-1 Ground floor layout

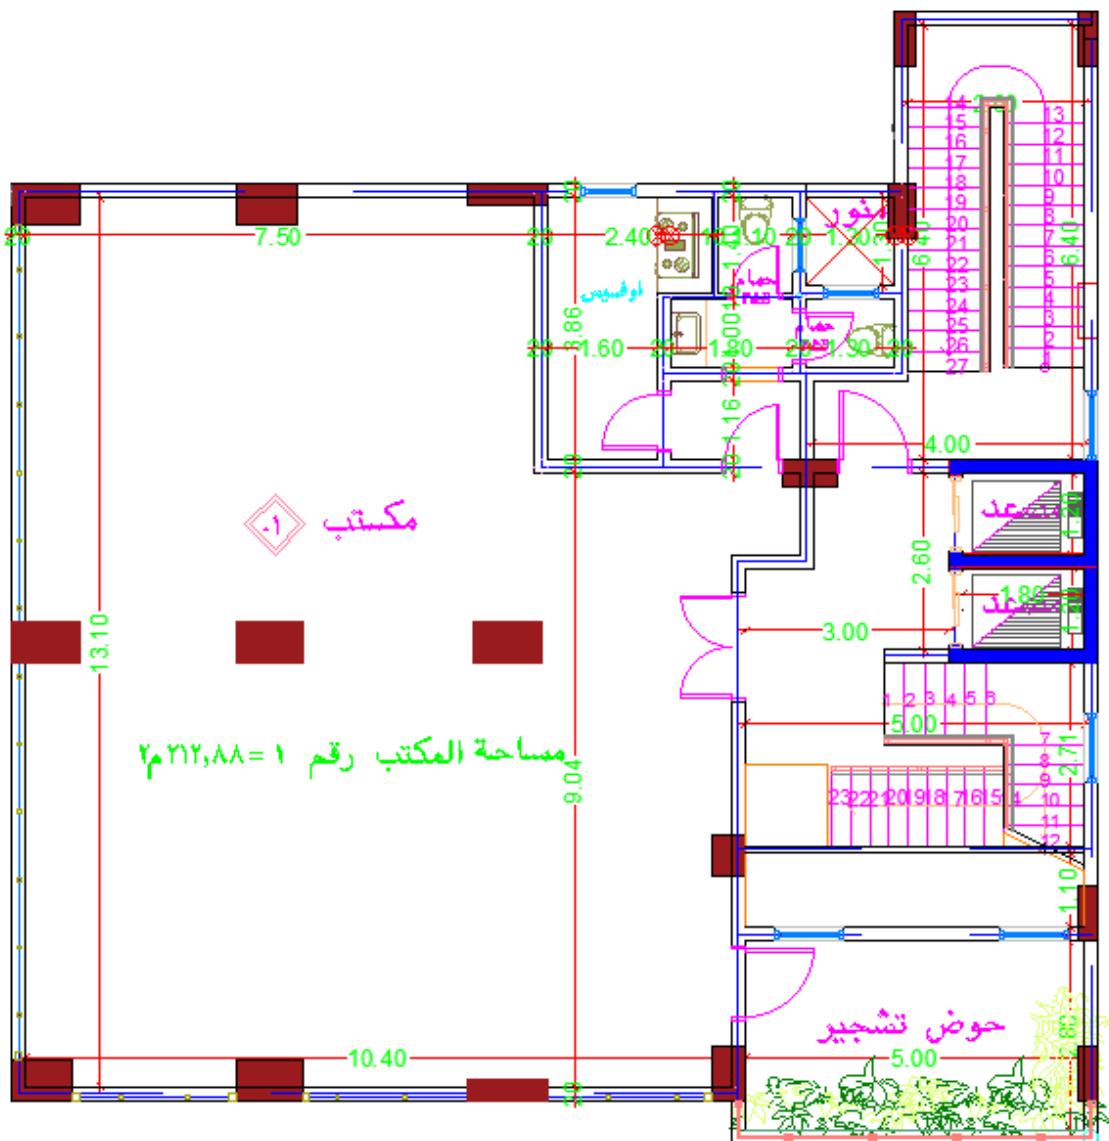

Figure 1-2: First Floor Layout

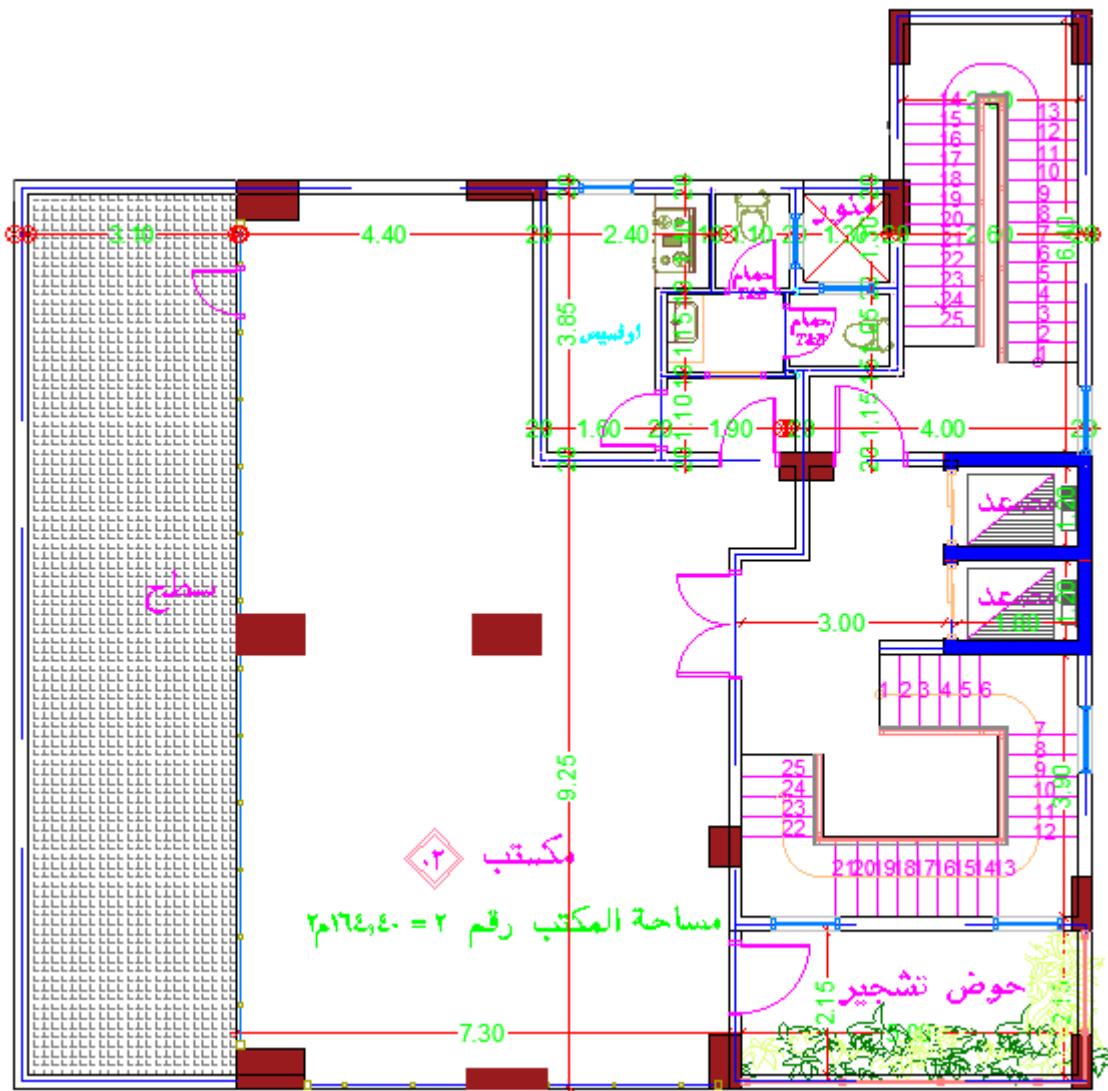

Figure 1-3: Second to the sixth Floor Layout

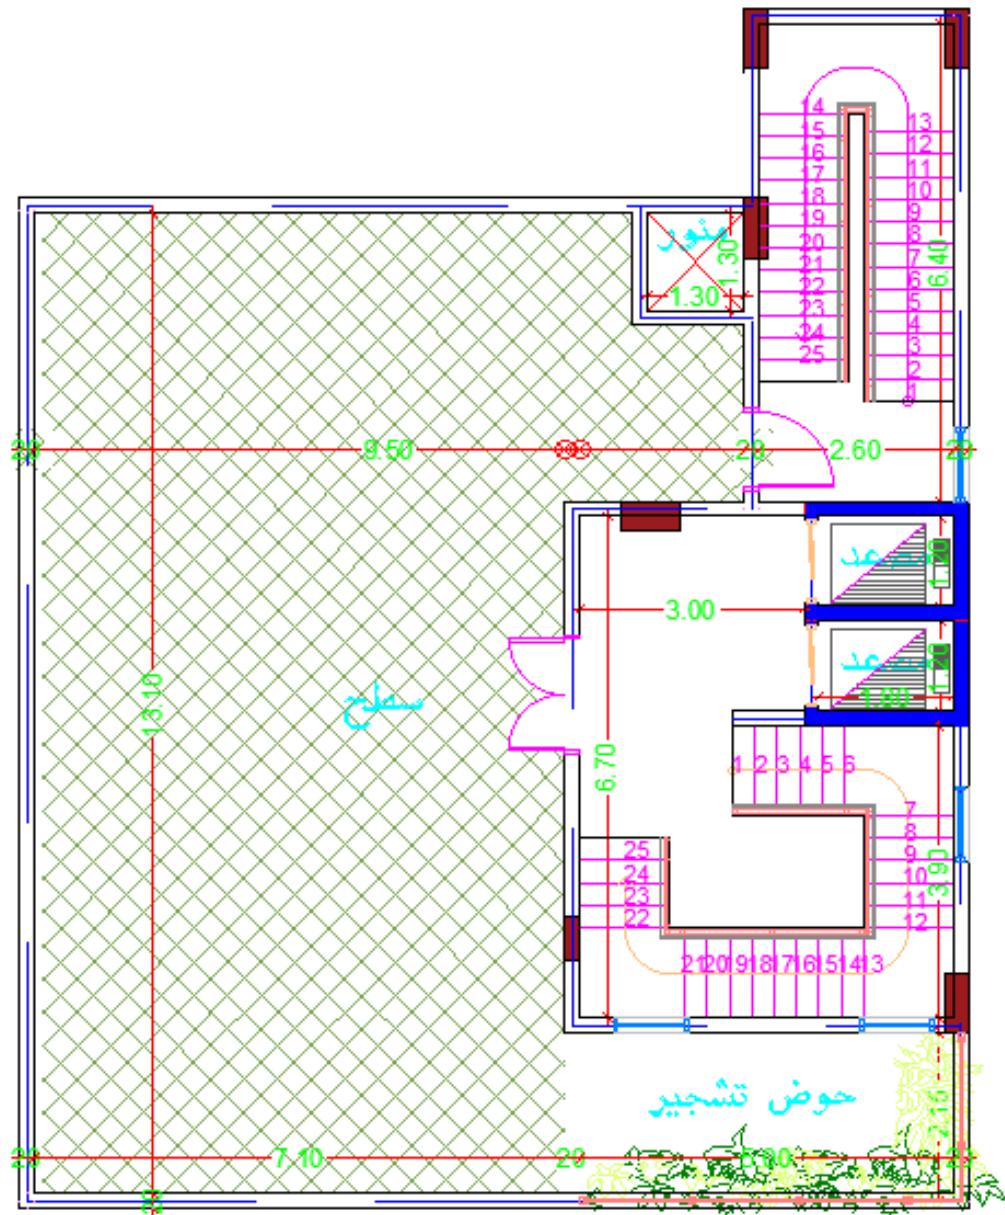

Figure 1-4: End Floor Layout

## **1.6. Project Objectives**

- Understand the architectural plane orientation.
- Design the structural system.
- Modeling and analysis using AutoCAD, ETABS, and REVIT software's

## **1.7. Outcomes**

The project outcomes are correlated to the program's outcomes stated by ABET. The level of achievement of each outcome depends on the nature of the SDP. It is expected that a student, who successfully completes the course, will demonstrate the following outcomes:

1. An ability to apply knowledge of mathematics, science, and engineering.
2. An ability to design and conduct experiments, as well as to analyze and interpret data.
3. An ability to design a system, component, or process to meet the desired needs within realistic constraints.
4. An ability to work in teams.
5. An ability to identify, formulates, and solves engineering problems.
6. An understanding of professional and ethical responsibility
7. An ability to communicate effectively.
8. An ability to engage in, life-long learning.
9. Knowledge of contemporary issues.
10. An ability to use the techniques, skills, and modern engineering tools necessary for engineering practice.
11. The application of all types of knowledge in the various engineering sciences, mathematics and physics on the ground.

## **1.8. Code of Practice:**

The design and analysis of the project had to go through verified standards:

- Saudi building code requirements for concrete structures (SBC 304- 2018)
- Saudi building code requirements for structural loading and forces (SBC301- 2018).
- American concrete institute requirements for reinforced concrete (ACI 318- 19)
- American concrete institute requirements for, reinforced concrete detailing (ACI 315- 04)

## CHAPTER 2. BUILDING DESCRIPTION

### 2.1. Structural Layout

Figures 2-1, 2-2, 2-3 and 2-4 show the structural plan for each story.

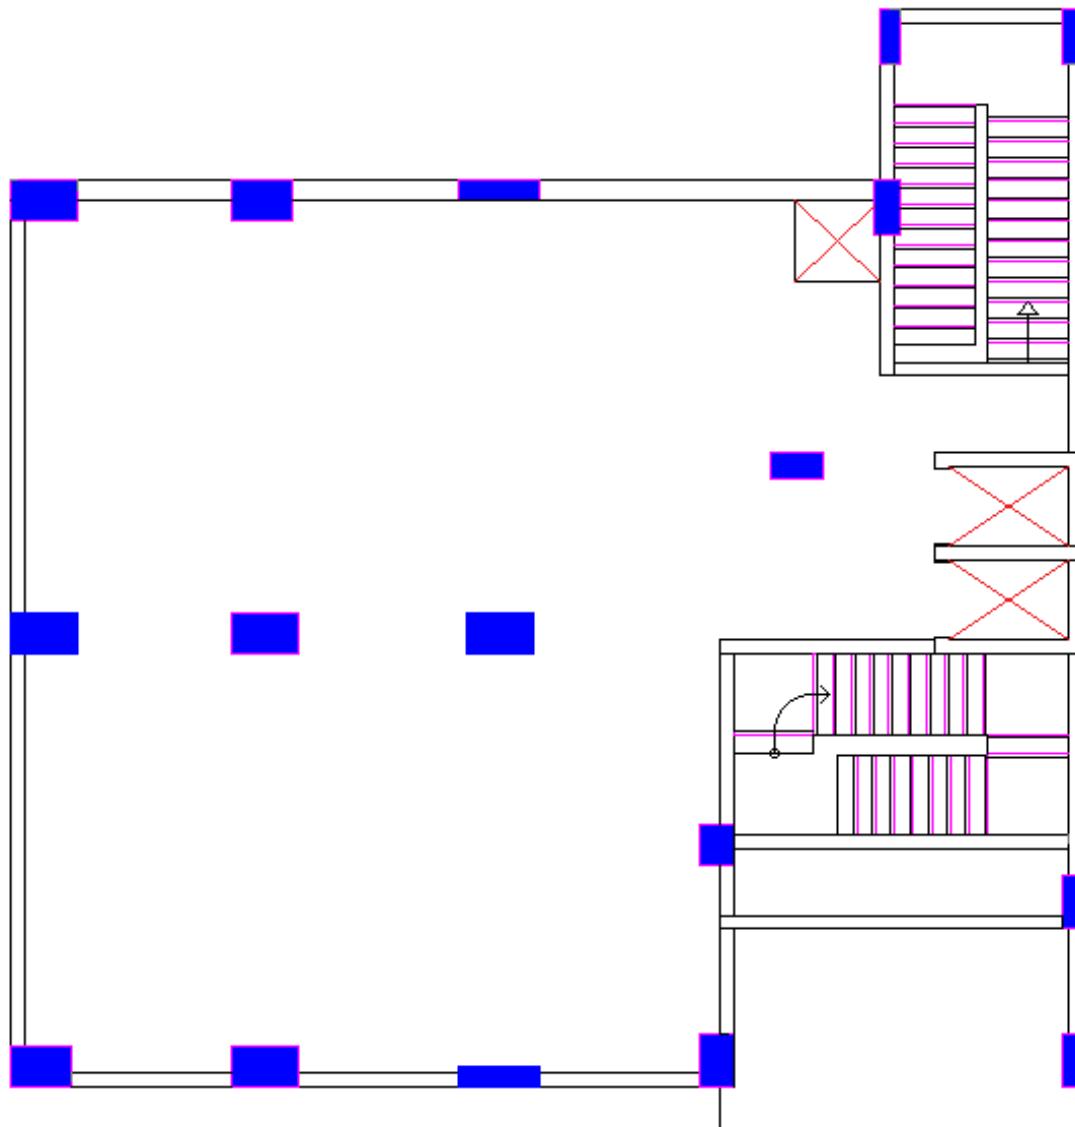

Figure 2-1: Ground floor

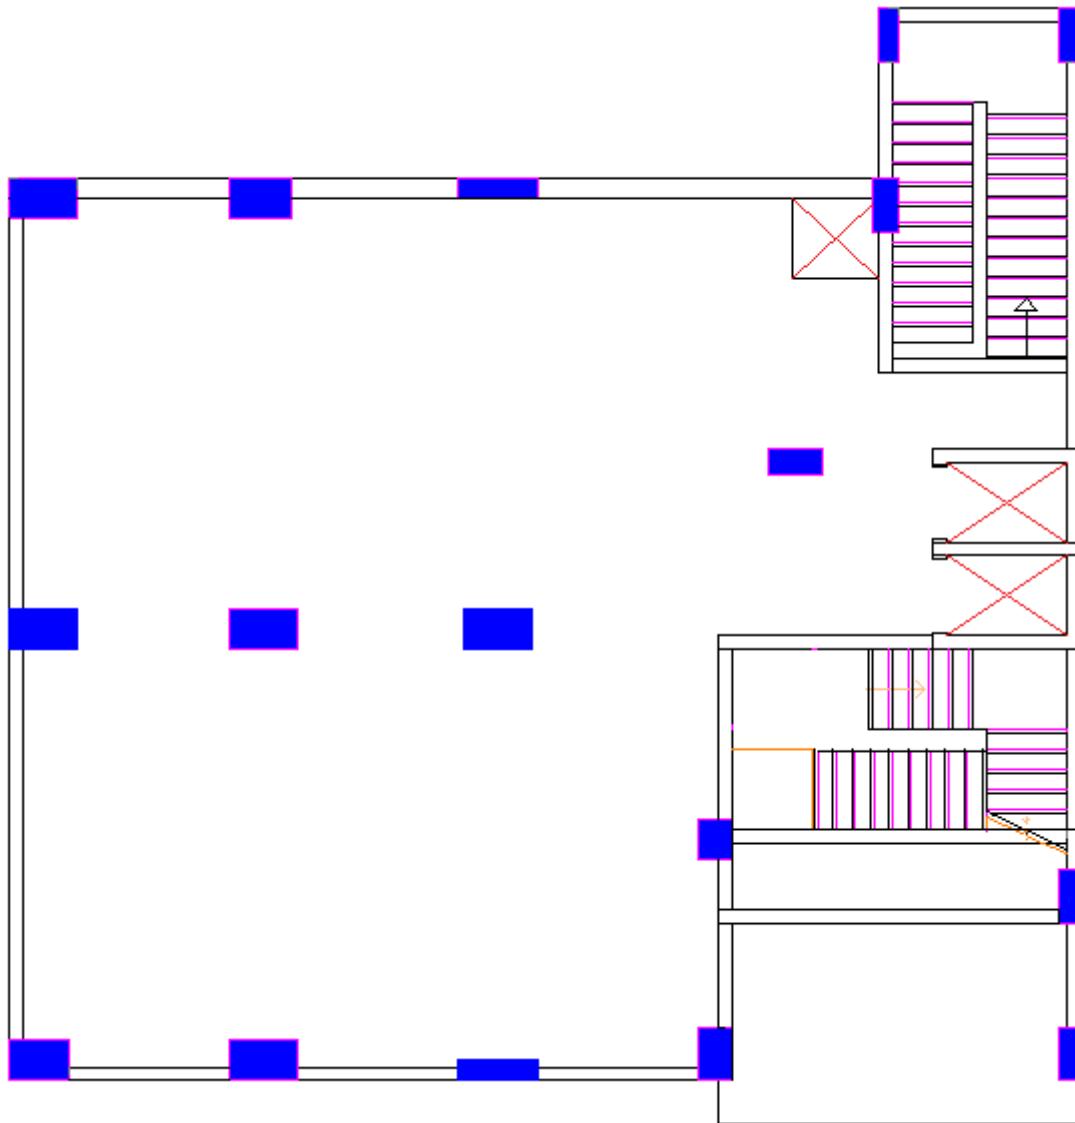

Figure 2-2: First floor

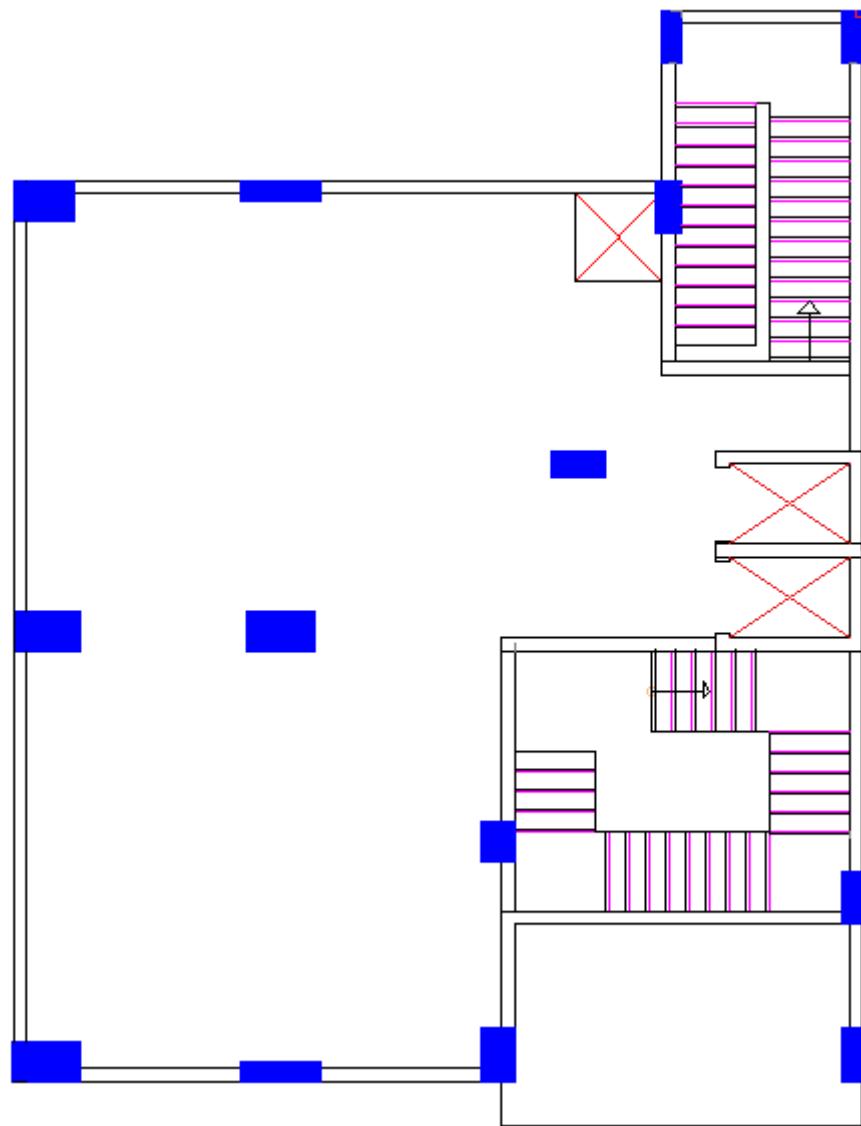

Figure 2-3: Second to the sixth floor

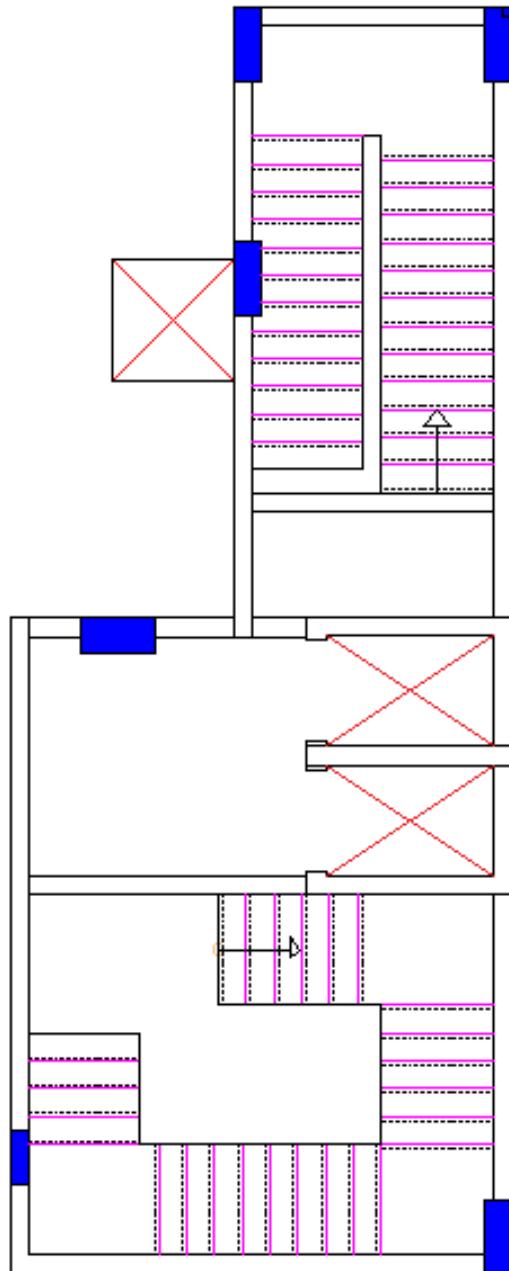

Figure 2-4 End floor

## 2.2. Materials

In construction, various material is used which among them wood, cement blocks, sand, aggregate, cement, concrete, and steel. However, this project focus primary on concrete and steel parameters.

### 2.2.1. Concrete

We all know that concrete can be an important and essential product in our lives for instance, it is used to provide strength, durability, and versatility during the construction of a structure. the raw material at which concrete is generally made are cement, aggregate, water, air mixed together at a different percentage for each sediment, inside a huge concrete mixer.

**The Compression Strength of Concrete ( $f'_c$ ):** is a measure of the concrete's ability to resist loads which tend to compress it.

The compressive strength of concrete chosen for design is 25 Mpa.

**Modulus of Elasticity of Concrete (Ec):** It is defined as the ratio between the normal stress to normal strain below the proportional limit.

Given by:

$$E_c = 4700 \times \sqrt{f'_c} \quad (2-1)$$

### 2.2.2. Rebar

Concrete is strong under compression, but has low tensile strength, rebar is used as a tension device in reinforced concrete and reinforced masonry structures to strengthen and aid the concrete under tension.

**Modulus of Elasticity of Steel (E):** is the slope of tensile stress-strain curve up to yielding limit.

**The Yield Strength of Steel ( $f_y$ ):** is the maximum stress that can be applied before it begins to change shape permanently.

The yield strength and modulus of elasticity chosen for design of steel are:  
( $f_y=400$  Mpa,  $E=200$  Gpa).

## **CHAPTER 3. LOADS**

The design of a building structure requires careful consideration of various types of loads that the structure may be subjected to. Loads, in the context of structural design, refer to the forces that act on the building, such as gravity, wind, and seismic activity. This section aims to provide a comprehensive overview of the different types of loads that need to be considered in the design of the building structure. In addition to the own weight of the building, the loads considered in this project include live load, wind load, and seismic load. Wind and seismic loads are determined manually and using ETABS software, which allows for accurate analysis and evaluation.

### **3.1. Gravity Load**

#### ***3.1.1. Dead load***

The dead loads are permanent loads which result from the weight of the structure itself or from other permanent attachments.

#### **Floor Loads (Flat Slab)**

---

$$W = \gamma \times ts = 25 \times 0.22 = 5.5 \text{ KN} / m^2 \quad (3-1)$$

*ETABS, automatically evaluate the own weight, therefore no need to use this value.*

---

Floor Finishes (Plaster, Sand, Mortar, ceramic, and Gypsum board). See Table 3-1.

$$W = 0.25 + (0.015 \times 70) + 1.1 + (0.01 \times 16) + 0.4 = 2.96 \text{ KN} / m^2 \quad (3-2)$$

Table 3-1 Minimum Design Dead Load [2]

Component	Load KN/m <sup>2</sup>
-----------	------------------------

Sand, per mm	0.015
Ceramic (20 mm) on a (25 mm) mortar bed	1.1
Plaster on concrete	0.25
Gypsum board, per mm thickness	0.01
Steel studs, 13 mm Gypsum board each side	0.4

### 3.1.2. *Live load*

Also known as applied or imposed loads, may vary over time, and often result from the occupancy of a structure. Typical live loads may include people, the action of wind on an elevation, furniture, vehicles and the weight of the books in a library.

As given in the SBC 303 (Table C4-1) [2] for office buildings use:

$$W = 2.5 \text{ KN/m}^2$$

For roof:

$$Wr = 1 \text{ KN/m}^2$$

### 3.1.3. *Member Loads (Walls)*

According to SBC 303 (Table C3-1) [2]:

For a 20×20×40 cm HCM  $\nabla b=16,5 \text{ KN/m}^3$

$$W = 16.5 \times (\text{height} \times \text{thickness}) = 16.5 \times (3.6 \times 0.2) = 11.88 \text{ kN / m}^2 \quad (3-3)$$

## 3.2. Wind Load

Wind is a major force that exerts pressure on the building, and if not properly accounted for; it may lead to structural failure. Following SBC301, wind loads on the Main Wind Force Resisting System (MWFRS) have been determined using Directional Procedure (DP).

The DP is applicable for all building heights; however, it could be applied if the building has a regular shape with absence of response characteristics making it susceptible to the effect of crosswind loading and vortex-induced forces, which unfortunately, is not achieved in this project. Nevertheless, the DP was manually applied to calculate the wind loads on the building and compared to the results obtained from ETABS software, considering the partial suitability of the procedure. This was done for further understanding and verification of the values obtained from the ETABS, considering minor difference.

General requirements are firstly obtained in accordance with SBC301. The design wind pressure ( $p$ ) acting on the building is then determined at all levels of stories of the building. Wind load cases are defined and illustrated in 3.2.3. Design wind loads cases. Excel spreadsheets were developed to compute wind forces in each story of the building considering all scenarios of the design wind load cases. Furthermore, a comparison between wind forces obtained from ETABS and spreadsheets were done and discussing the minor differences due to partial suitability of the DP to determine design wind loads for irregular building structure.

### ***3.2.1. General requirements for determining wind loads***

These requirements are the basic parameters used for determining wind loads on the (MWFRS) and other components of the building. The basic parameters encompass, Ultimate wind speed (V), Wind directionality factor

( $K_d$ ), Exposure category, Topographic factor ( $K_{zt}$ ), Gust effect factor, Enclosure classification, and Internal pressure coefficient ( $GC_{pi}$ ) were obtained from A-2 , A-3 , A-4 , A-5 , A-6 , A-7 , and A-8 respectively. To assess these parameters, it is required to determine the Risk category of the building based on the SBC301, which has been found to be II category as shown in A-1 . Table 3-2 represents values of each of these parameters obtained from SBC301.

Table 3-2 Basic parameters for determining wind loads on the MWFRS

Parameter	value
Ultimate wind speed, V	47 m/s
Wind directionality factor, $K_d$	0.85
Exposure Category	C
Topographic factor, $K_{zt}$	1
Gust-effect factor, G	0.85
Enclosure classification	Enclosed
Internal pressure coefficient, $GC_{pi}$	$\pm 0.18$

### 3.2.2. Calculation of the design wind pressure for the MWFRS

After obtaining the basic parameters required for determining wind loads on the MWFRS, the velocity pressure ( $q_z$ ) is then calculated at various height of the building ( $z$ ) by equation (3-4). It shall be noted that the velocity pressure at mean roof height ( $h$ ) is referred as ( $q_h$ ). Therefore, the design wind pressure on the windward walls, leeward walls, and side walls were defined for all heights of the building by equation (3-5).

$$q_z = q_h = 0.613 K_z K_{zt} K_d V^2 \quad (3-4)$$

Where:

$K_z$ : Velocity pressure exposure coefficient

$K_{zt}$ : Topographic factor

$K_d$ : Wind directionality factor

V: Ultimate wind speed, (m/s)

$q_z$ : Velocity pressure at height z, ( $N/m^2$ )

$q_h$ : Velocity pressure at mean roof height h, ( $N/m^2$ )

The design wind pressure is then determined by the following equation:

$$p = qGC_p - q_h(GC_{pi}) \quad (3-5)$$

Where:

$q=q_z$  for windward evaluated at height z

$q=q_h$  for leeward walls, side walls, and roof evaluated at mean roof height

G: Gust-effect factor

$C_p$ : External pressure coefficient

$(GC_{pi})$ : Internal pressure coefficient

### 3.2.3. Design wind loads cases

The MWFRS shall be designed for the wind load cases those defined in SBC301. The design wind load cases consider the application of wind pressure on the building from different direction, considering eccentricity moment and whether the pressure is applied simultaneously on walls or not. The design can be based on full design pressure or 75% of it. These various cases are illustrated in A-9 .

For each of these cases, it shall be considering the direction of the wind either the wind is on the x-axis or y-axis and considering positive and negative eccentricity if the case containing moment. Therefore, total number of twelve cases are developed as shown in Table 3-3. It shall be noted that the direction of the wind, affecting value of ( $C_p$ ); since it is a function of ( $L/B$ ), where B is the dimension perpendicular to wind pressure.

Table 3-3 The design wind load cases

Code case No.	Case No	Wind direction	Eccentricity ratio, $e_y$	Eccentricity ratio, $e_x$
1	1	x-axis	0	0
	2	y-axis	0	0
2	3	x-axis	0.15	0
	4	x-axis	-0.15	0
	5	y-axis	0	0.15
	6	y-axis	0	-0.15
3	7	x-axis	0	0
	8	y-axis	0	0
4	9	x-axis	0.15	0.15
	10	x-axis	-0.15	-0.15
	11	y-axis	0.15	0.15
	12	y-axis	-0.15	-0.15

### 3.2.4. Excel spreadsheet and ETABS results for wind load

Excel spreadsheets were developed for the purpose of computing the design wind forces on each story of a building. These spreadsheets possess an automated functionality, allowing them to be utilized for different buildings simply by modifying the input data.

Figures 3-1, and 3-2 show the input data sheet. The design wind pressure on windward wall and leeward wall is shown in figures 3-3 and 3-4. And the story forces for all wind load cases are calculated; however, the wind forces for case #1 is shown in Figure 3-5 to be compared with the wind forces determined by ETABS. Figure 3-6 shows the modifying window of wind load pattern in ETABS, and it is shown that all twelve cases are created. Comparison of results obtained from ETABS, and the spreadsheet is illustrated in Table 3-4. The analysis reveals an average relative error 3.5% which is believed to arise due to partial suitability of the applied method DP to computing wind loads. To be

engaged in knowledge, a simple model with a regular shape and eight story building were developed and calculating wind forces on it; the outcomes obtained from ETABS, and manual calculation were remarkably similar and almost identical as shown in Figure 3-8, and Table 3-5.

### 3.3. Seismic Load

Seismic loads refer to the forces exerted on a structure during an earthquake or seismic event. These loads are caused by the ground shaking, ground displacement, and other seismic effects that occur due to the release of energy in the Earth's crust.

#### 3.3.1. *Earthquake maps*

To commence, we need to ascertain the Mapped Spectral response acceleration ( $S_s$ ) and Mapped Spectral response acceleration ( $S_1$ ) by referring to the seismic maps provided in the SBC 301. Figure 3-9 and Figure 3-10 show  $S_s$  and  $S_1$  maps where the red dot represents the building location.

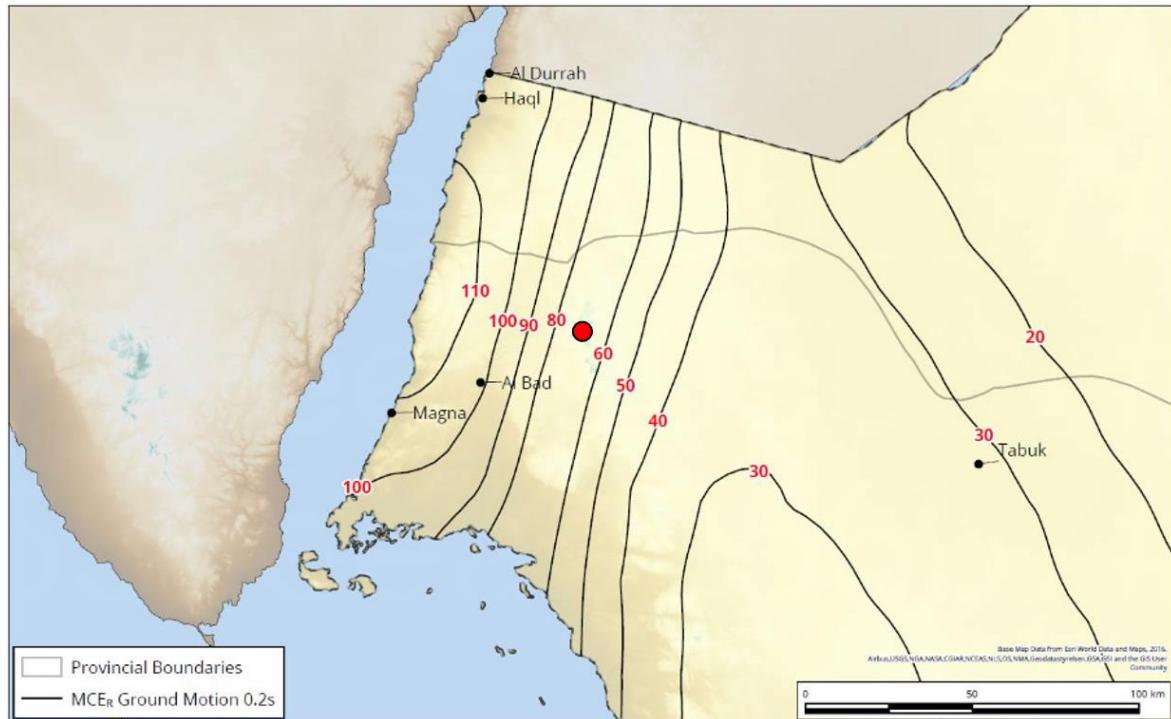

Figure 22-1a: S<sub>s</sub> Risk-Targeted Maximum Considered Earthquake (MCE<sub>R</sub>) ground motion for 0.2 s spectral response acceleration (5% of critical damping), site class B, North-West (NW-SA).

Figure 3-9 Spectral response acceleration (S<sub>s</sub>)

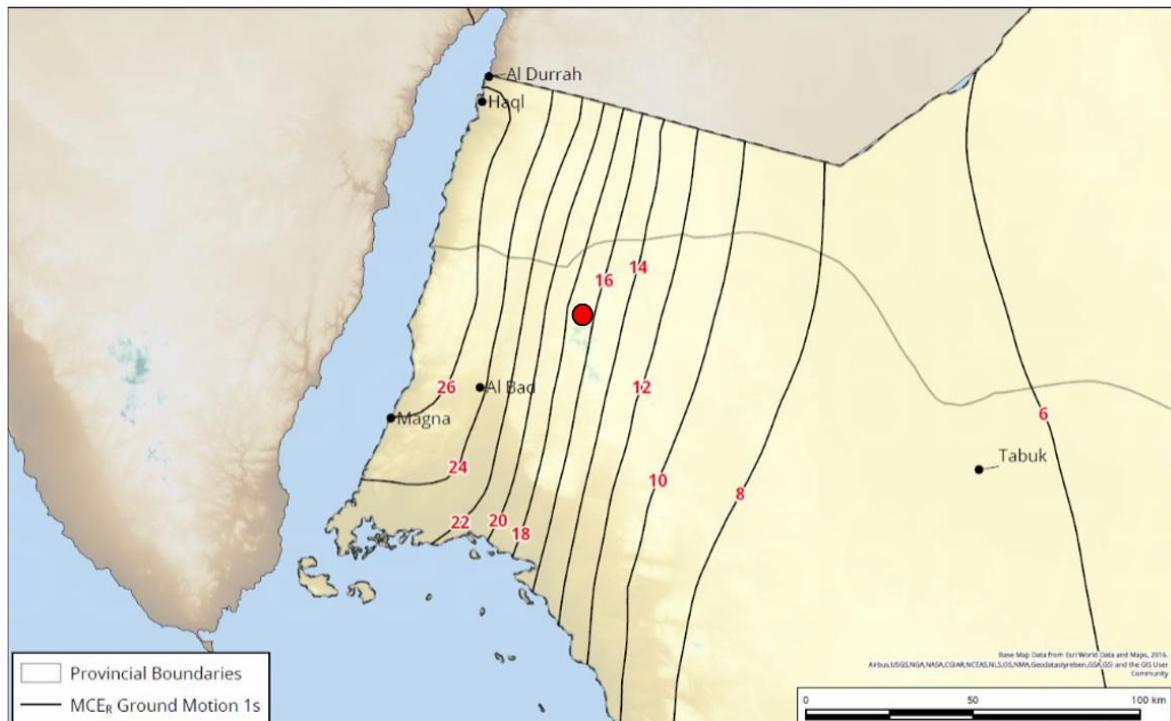

Figure 22-2a: S<sub>1</sub> Risk- Targeted Maximum Considered Earthquake (MCE<sub>R</sub>) ground motion parameter for 1 s spectral response acceleration (5% of critical damping), site class B, North-West (NW-SA)..

Figure 3-10 Spectral response acceleration (S<sub>1</sub>)

### 3.3.2. Equations and parameters

The needed equations to calculate the seismic loads are as follows:

- ❖ The spectral response acceleration parameters for short periods ( $S_{ms}$ ) and at 1 second ( $S_{m1}$ ):

$$S_{ms} = F_a \times S_s \quad (3-6)$$

$$S_{m1} = F_v \times S_1 \quad (3-7)$$

Where:

$S_{ms}$  &  $S_{m1}$ : are adjusted response parameters -site class effect (Short period & at 1 second period).

$F_a$  &  $F_v$ : are site coefficient and their values are obtained from SBC 301, Tables 11-1 and 11-2.

- ❖ Earthquake spectral response acceleration parameters at short period ( $S_{DS}$ ) and at 1 second period ( $S_{D1}$ ):

$$S_{DS} = \frac{2}{3} \times S_{ms} \quad (3-8)$$

$$S_{D1} = \frac{2}{3} \times S_{m1} \quad (3-9)$$

Where:

$S_{DS}$  &  $S_{D1}$ : are design spectral response acceleration parameter (Short period and at 1 second period).

- ❖ Seismic base shear:

$$V = C_s \times W \quad (3-10)$$

$$C_s = \frac{S_{DS}}{(R / I_e)} \quad (3-11)$$

The value of  $C_s$  calculated above should not exceed the following:

$$C_s = \frac{S_{D1}}{(T \times (R / I_e))} \quad \text{For } T \leq T_L \quad (3-12)$$

$$C_s = \frac{S_{D1} \times T_L}{(T^2 \times (R / I_e))} \quad \text{For } T \geq T_L \quad (3-13)$$

And  $C_s$  shall not be less than:

$$C_s = 0.044 \times S_{DS} \times I_e \geq 0.01 \quad (3-14)$$

Where:

V: The seismic base shear (kN).

$C_s$ : Seismic Response Coefficient.

W: The effective seismic weight per Section.

R: Response modification coefficient (SBC 301, table 12-1).

$I_e$ : Importance Factor (Table 1-3).

T: Fundamental T obtained from ETABS.

$T_L$ : Long Period-transition period (SBC 301, Figure 22.4)

❖ Vertical distribution of seismic forces:

$$F_x = C_{vx} \times V \quad (3-15)$$

$$C_{vx} = \frac{w_x \times h_x^k}{\sum_{i=1}^n w_i \times h_i^k} \times h_n \quad (3-16)$$

Where:

$F_x$ : Lateral seismic force (kN).

$C_{vx}$ : Vertical distribution factor.

$w_x$ ,  $w_i$ : Portion of weight that is located at or assigned to level i or x.

$h_x$ ,  $h_i$ : The height above the base to level i or x respectively.

k: Distribution exponent (Sec 12.8.3)

$h_n$ : Structural height.

❖ Approximate fundamental period:

$$T_a = C_t \times h_n^x \quad (3-17)$$

Where:

$T_a$ : Approximate fundamental period (SBC 301, 12.8.2.4.1 - Equation 12-18).

$C_t$ : Approximate period parameter (SBC 301, Table 12-7).

x: Approximate period parameter (SBC 301, Table 12-7).

### 3.3.3. *Excel sheets and ETABS results for seismic load*

A spreadsheet was created in Excel to calculate the lateral seismic forces acting on the building as per the SBC code. The results were then compared with the results obtained from ETABS, as the following figures show:

# CHAPTER 4. DESIGNING OF BUILDING STRUCTURE

## 4.1. Design Steps

- ❖ Definition of the layout in plan and height of the structure.
- ❖ Calculation of the gravity and lateral loads that act on the structure.
- ❖ Definition of an appropriate floor system.
- ❖ Setting the dimensions of beams and the thickness of slabs.
- ❖ Calculation of the reinforcement for all the members.
- ❖ Production of the structural drawings and specification.

## 4.2. Defining the materials

Figures 4-1, 4-2, 4-3 and 4-4 show the material defined in ETABS.

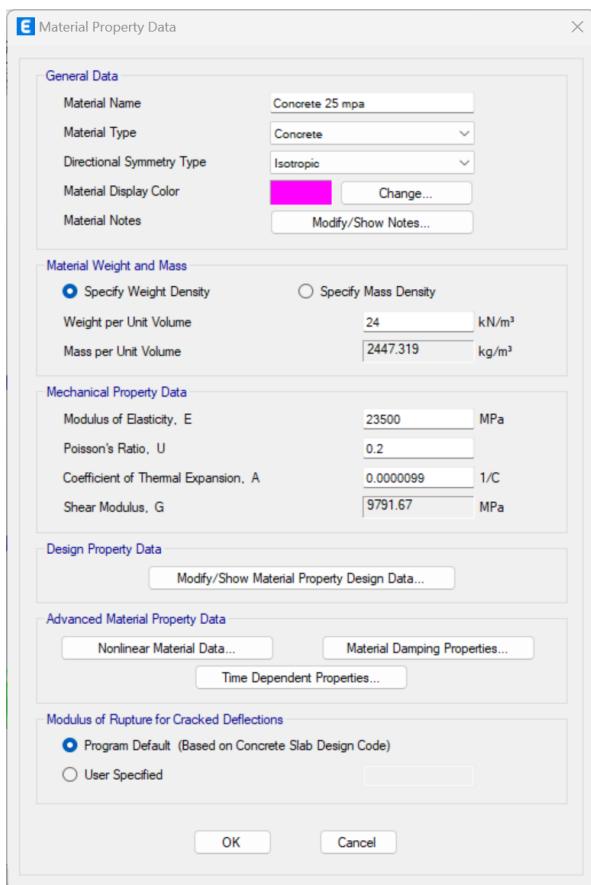

Figure 4-1 Concrete property

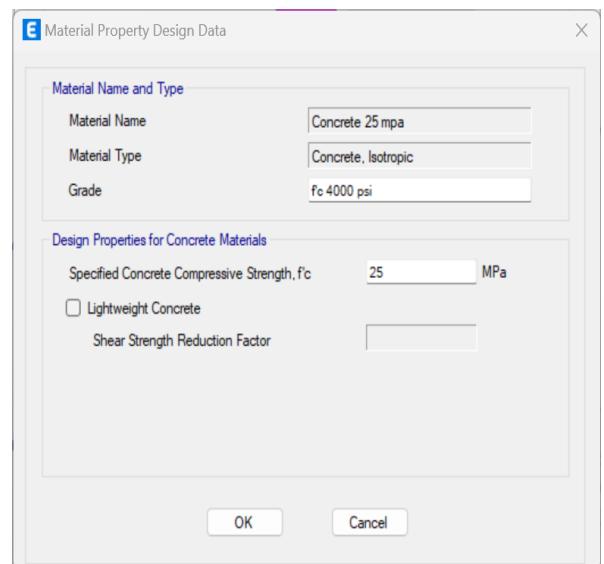

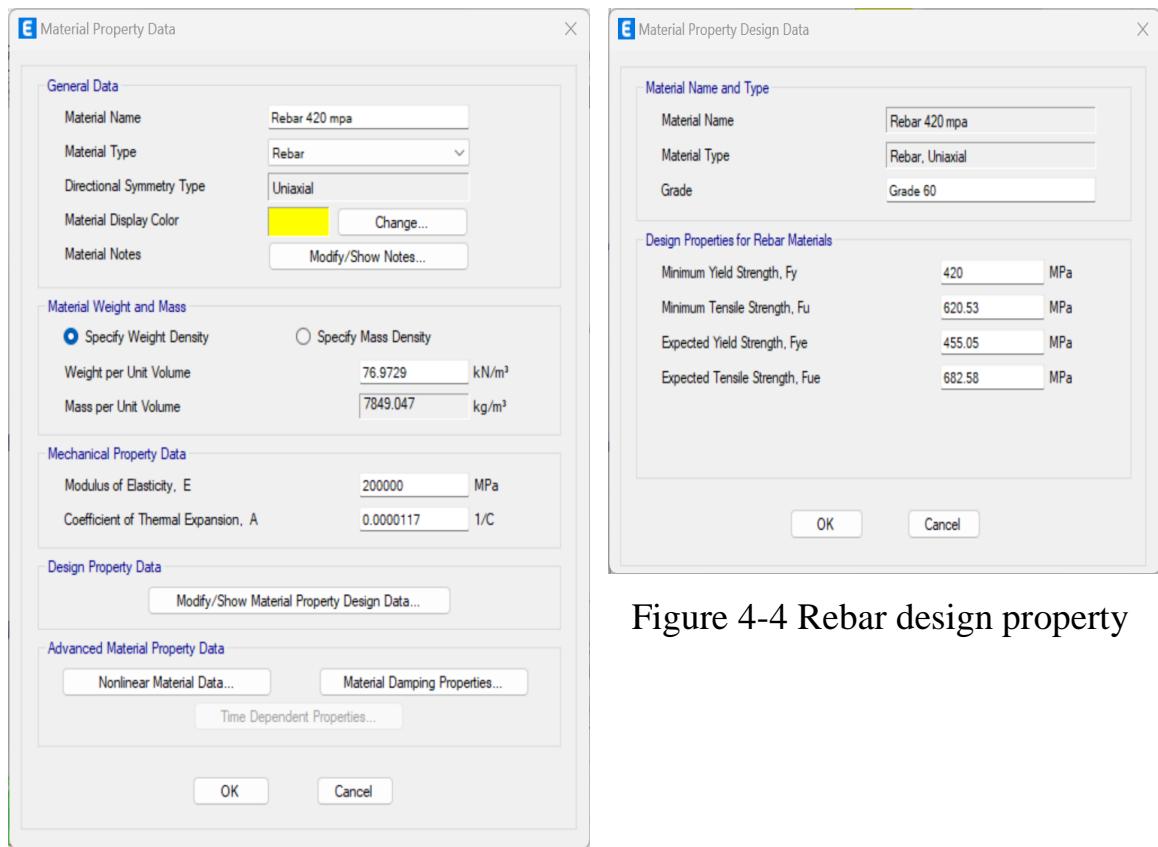

Figure 4-2 Concrete design property

## 4.3. Defining the structural system

### 4.3.1. Beams

Figure 4-5 shows the beam property.

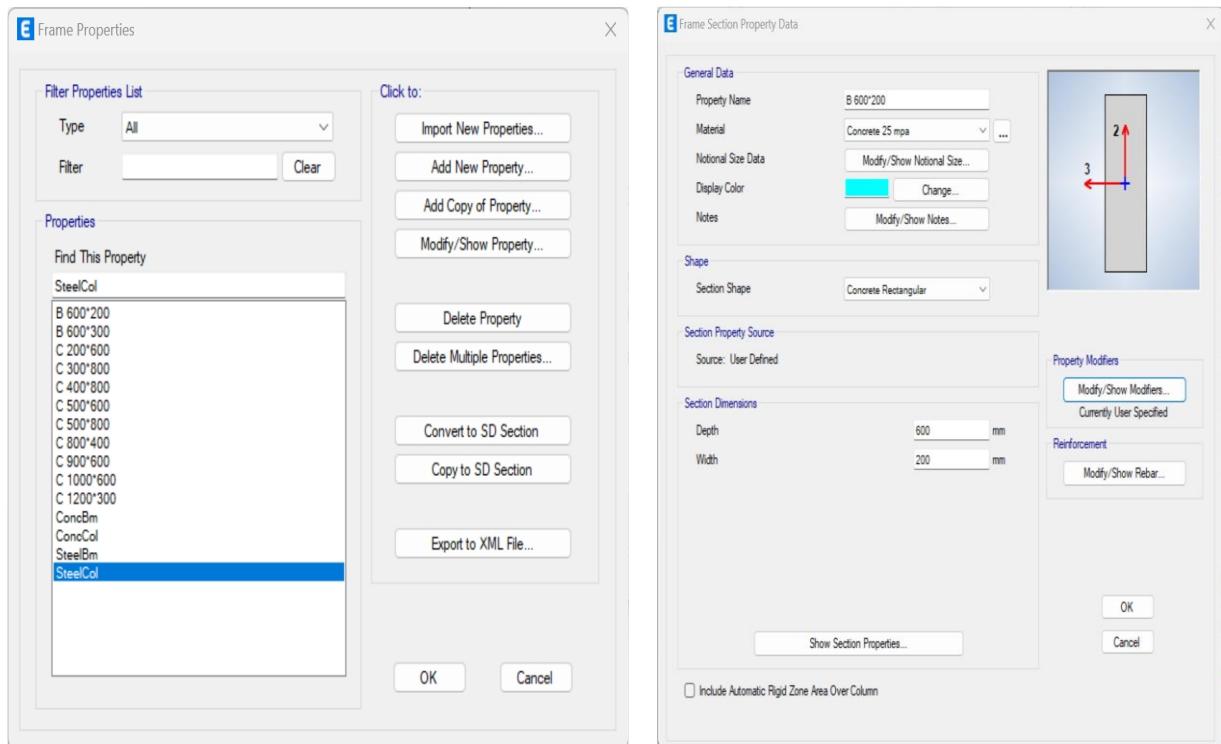

Figure 4-5 Beam property

### 4.3.2. Columns

The column sizes were given in the architectural plan as mentioned in chapter 1. Figure 4-6 shows the column property.

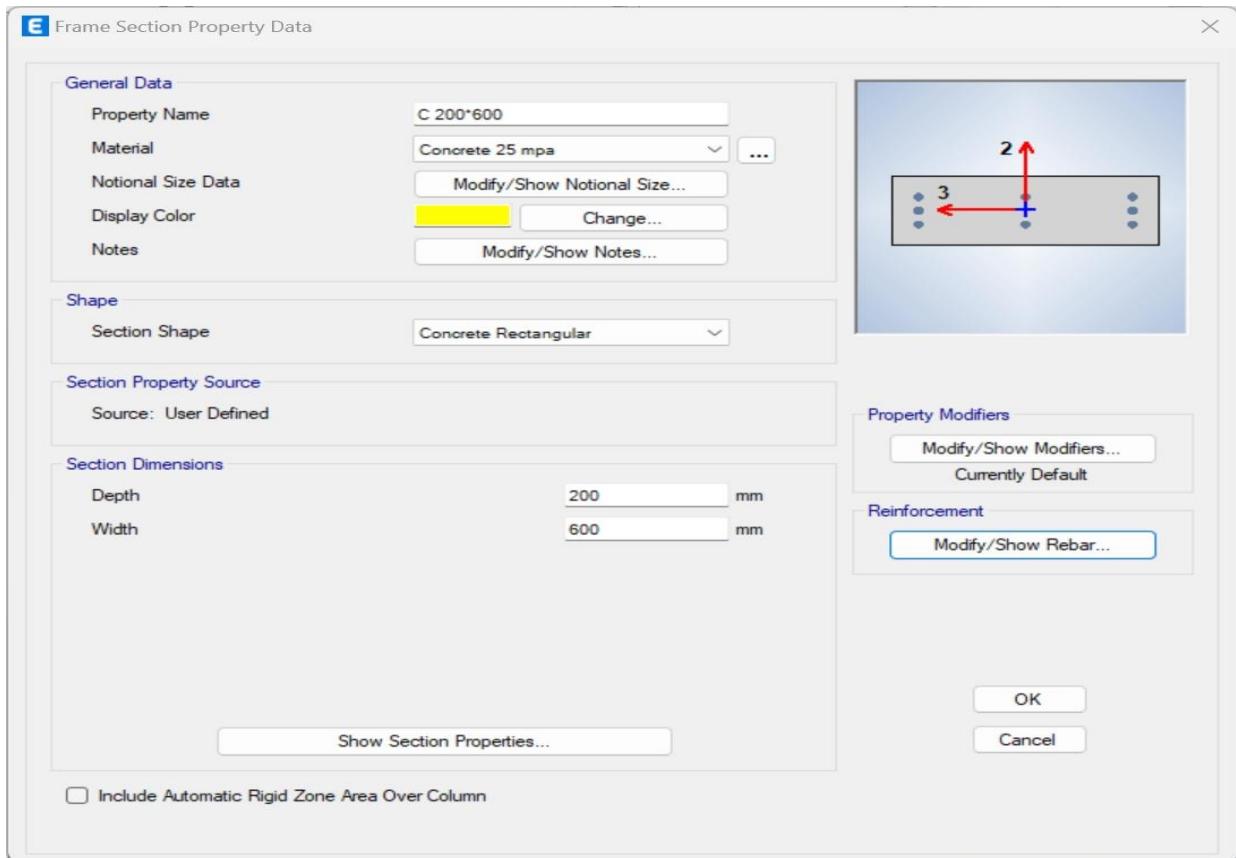

Figure 4-6 Column Property

#### 4.3.3. Slabs

There will be two models for design in this project one with flat slab and the other with solid. The minimum thickness for flat slab for edge beam without drop panels is [1]:

$$M_n = \Phi \times A_s \times f_y \times \left( d - \frac{a}{2} \right) \quad (4-1)$$

Where:

$L_n$ : The maximum clear span.

The thickness for the flat slab is 220 mm (because the long-term deflection is not in the boundary with less thickness) and for the solid slab 180 mm is selected for its thickness. Figures 4-7 and 4-8 show the slab properties.

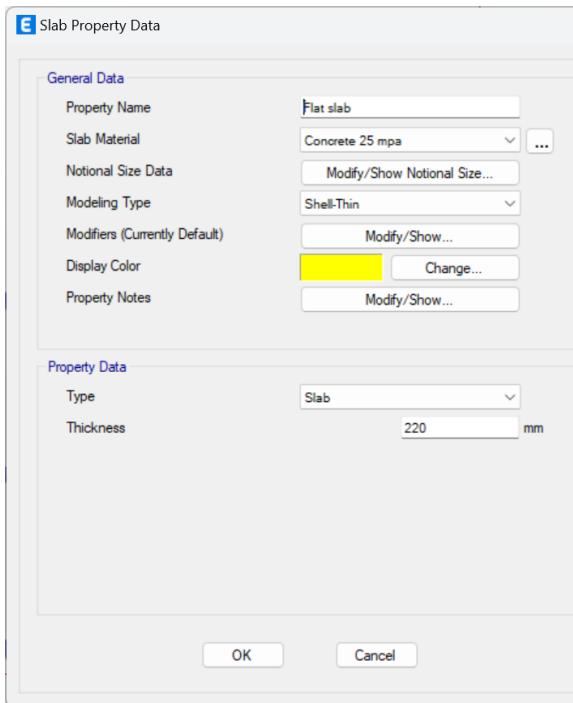

Figure 4-7 Flat slab property

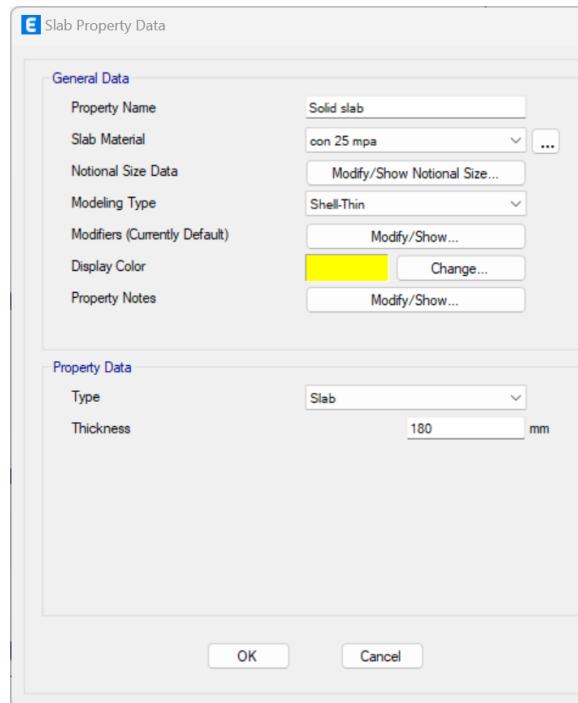

Figure 4-8 Solid slab property

#### 4.3.4. Shear walls

Structural shear walls are vertical elements designed to resist lateral loads and distribute them to the building's foundation, providing stability and reducing the building's sway during seismic events or wind forces. Figure 4-9 shows the defining of the piers.

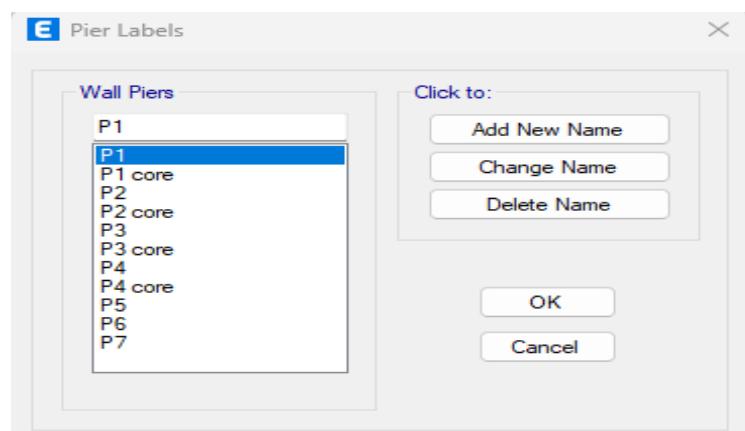

Figure 4-9 Defining piers

#### 4.4. Check model

Once the DXF file has been imported and all the elements have been drawn, it is important to check the model for any warnings. It is better to address any issues early on. Figure 4-10 shows the model check.

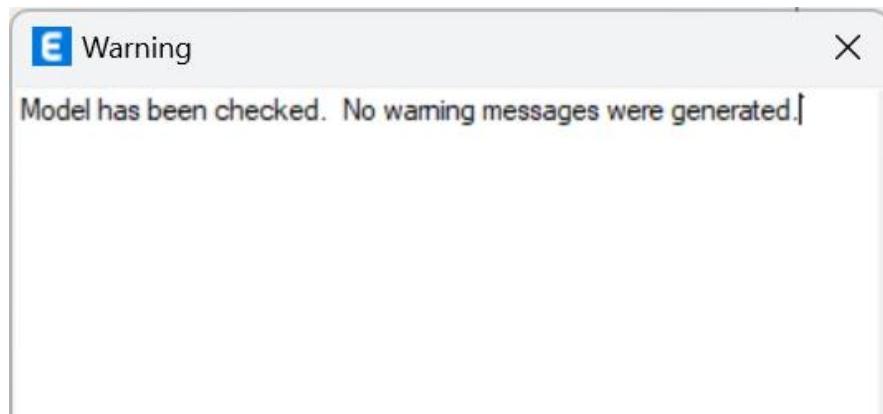

Figure 4-10 Model check

#### 4.5. Defining and assigning the loads

##### 4.5.1 Load patterns

Figure 4-11 shows the load patterns set in ETABS. 1 selected for the own weight meaning that the etabs will calculate the own weight of the structure.

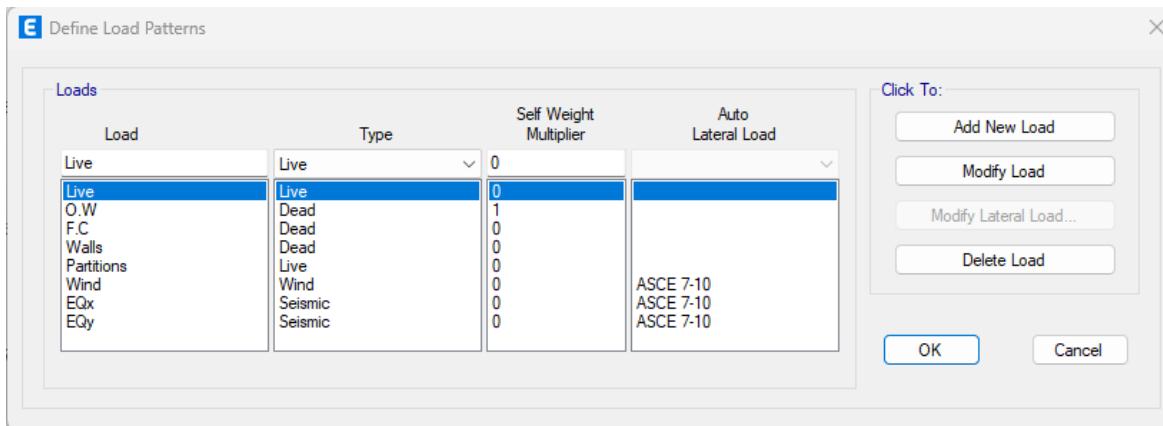

Figure 4-11 Load patterns

#### **4.5.2. Load combination**

Figure 4-12 shows the load combination inserted in etabs. The ultimate load which is [1.4 D.L + 1.7 L.L] is the one that will be used for the design.

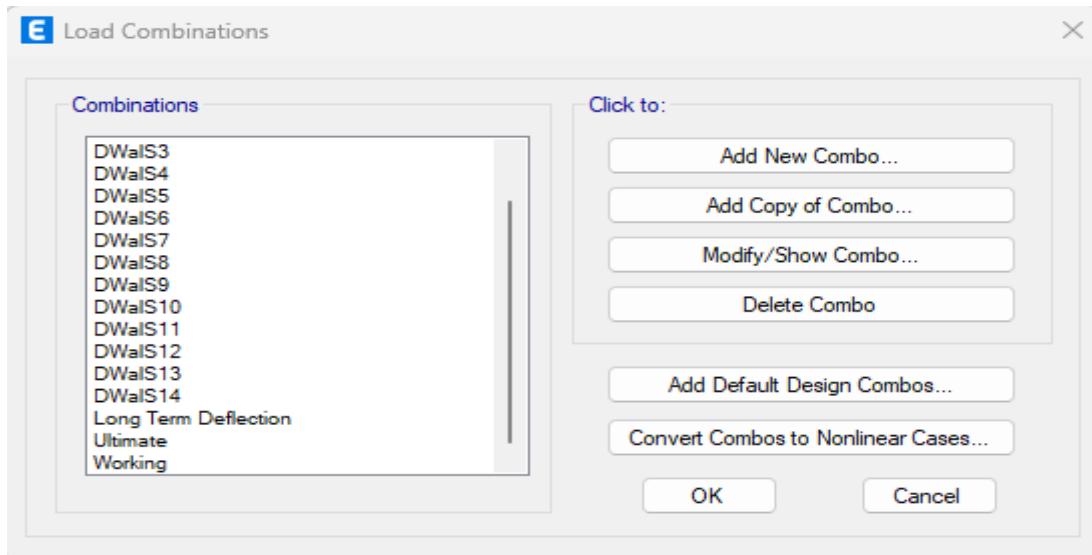

Figure 4-12 Load combination

#### **4.5.3. Assigning the loads**

The loads that are calculated in chapter 3 are assigned in etabs. Figures 4-13, 4-14, 4-15 and 4-16 show the shell loads assigned in etabs.

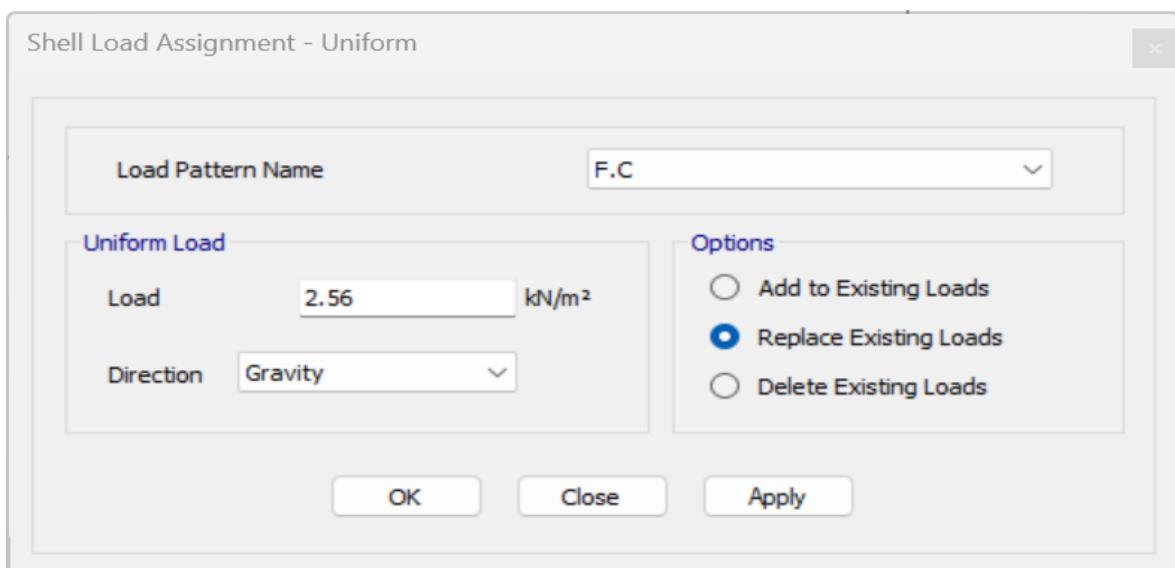

Figure 4-13 Floor finishes

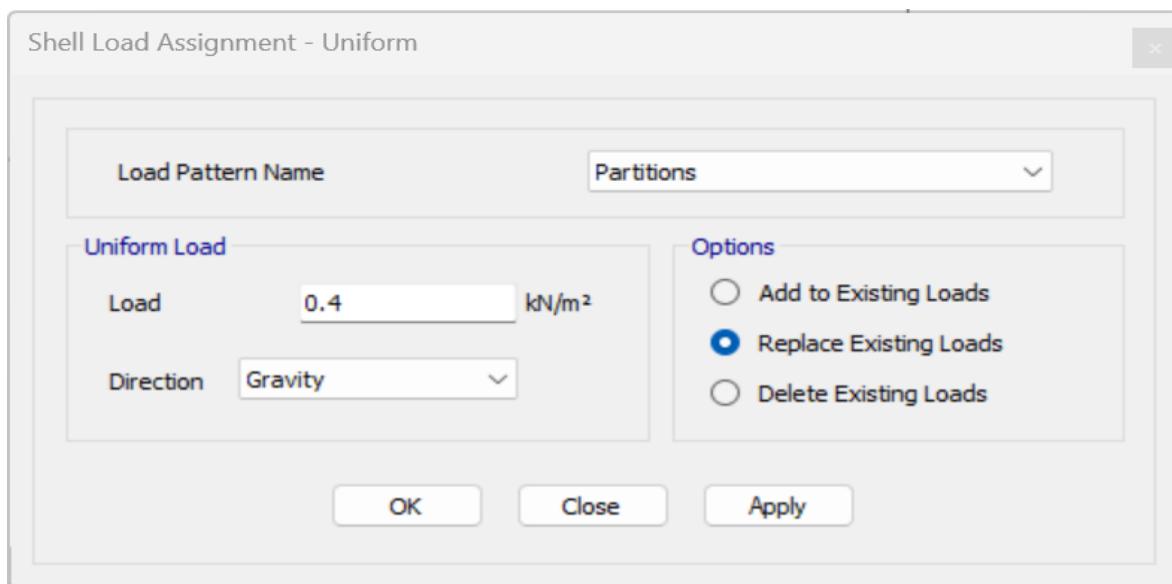

Figure 4-14 Partition

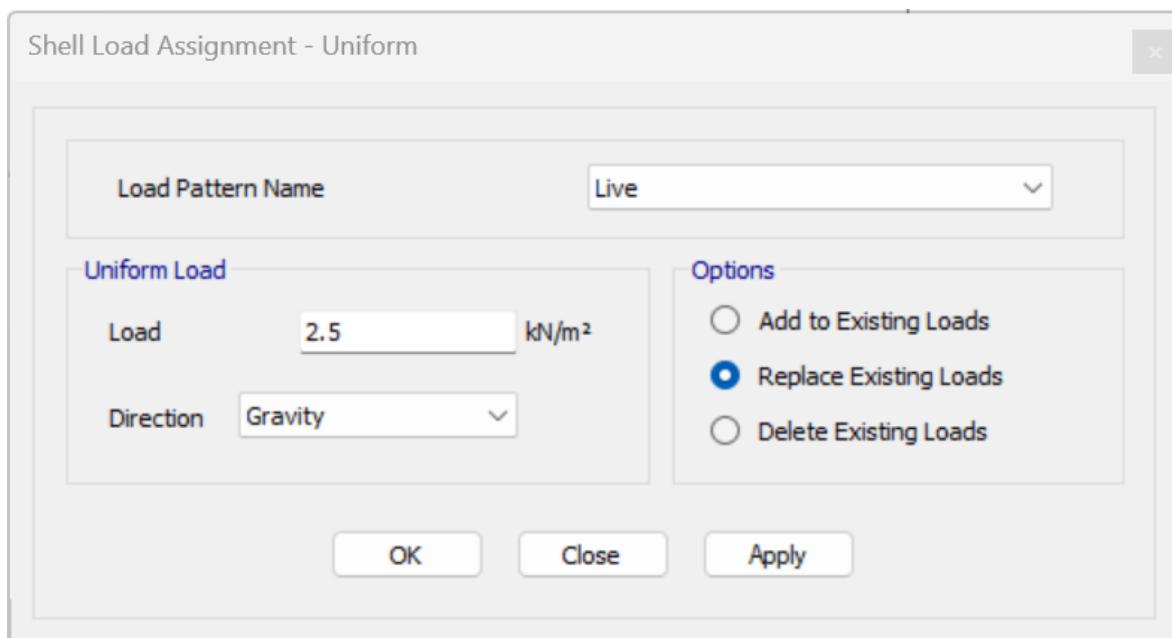

Figure 4-15 Live loads for the floors

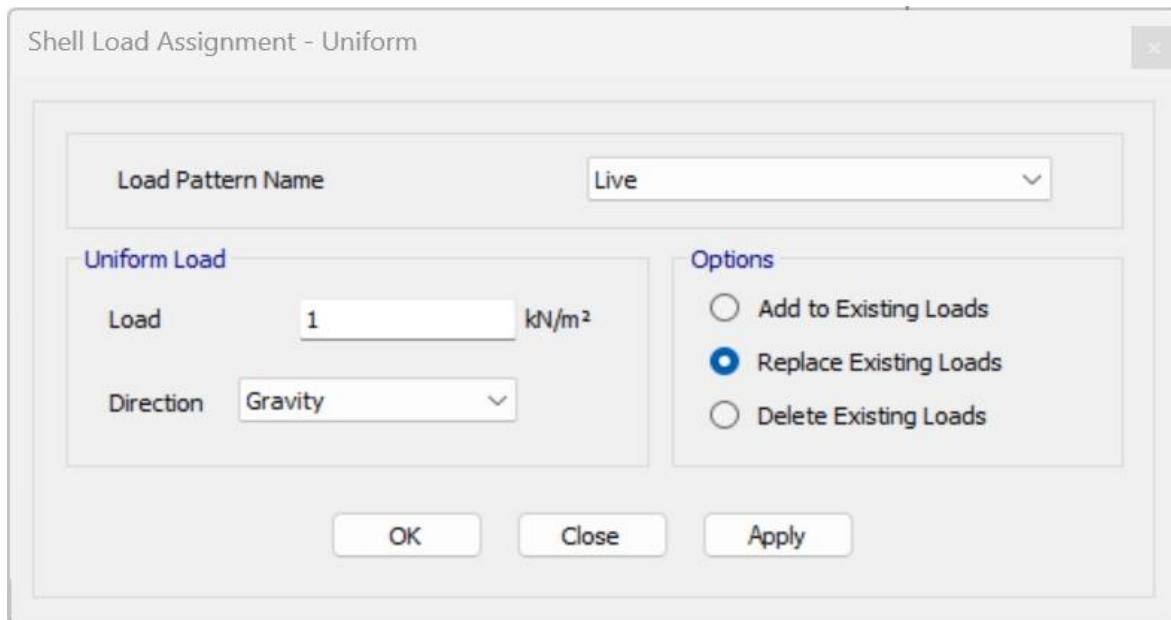

Figure 4-16 Live load for the roofs

Figure 4-17 shows the load of the edge walls that are assigned to the beams.

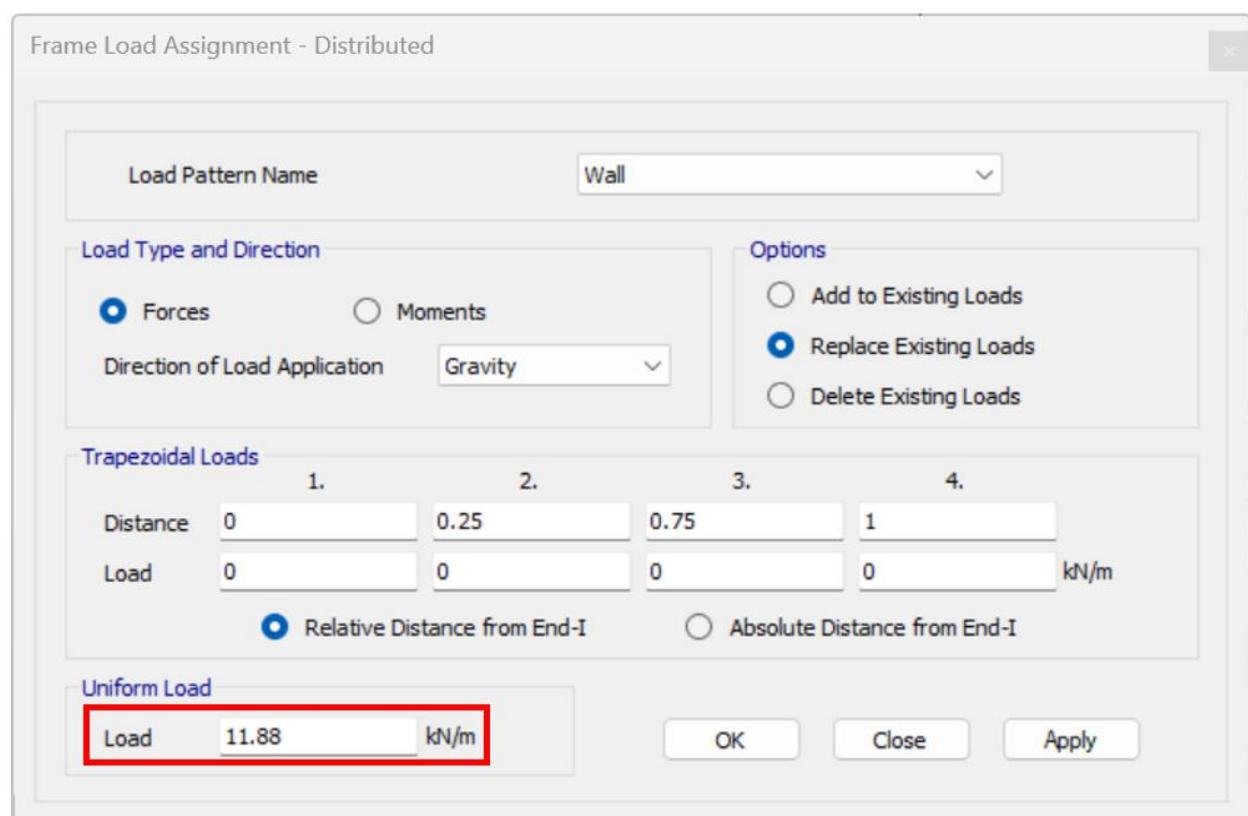

Figure 4-17 Walls load

#### **4.6. Check long term deflection**

According to the SBC 304 [1] maximum permissible computed deflection for a roof or floor construction supporting or attached to nonstructural elements not likely to be damaged by large deflections is:

$$\frac{L_n}{240} = \frac{6150}{240} = 25.625\text{ mm}$$

Where L is the maximum span length between the faces of the support. Long term deflection: Short-term deflection refers to the immediate deformation of a structural building member under applied loads, while long-term deflection refers to the gradual deformation that occurs over time due to factors such as creep and shrinkage of the materials. According to ACI 318 [3],

**LONG TERM DEFLECTION**— is the summation of immediate deflection for 75% Live load: (Dead Load + Superimposed Dead Load + Live Load) – (Dead Load + Superimposed Dead Load + 0.25 Live Load) and Long-Term Deflection for Dead Load + Superimposed Dead Load + 25% Sustained Live Load. To calculate it in ETABS, there are three cases that have to be defined:

##### **4.6.1 Case 1: Immediate all loads:**

Figure 4-18 shows the load data for case 1.

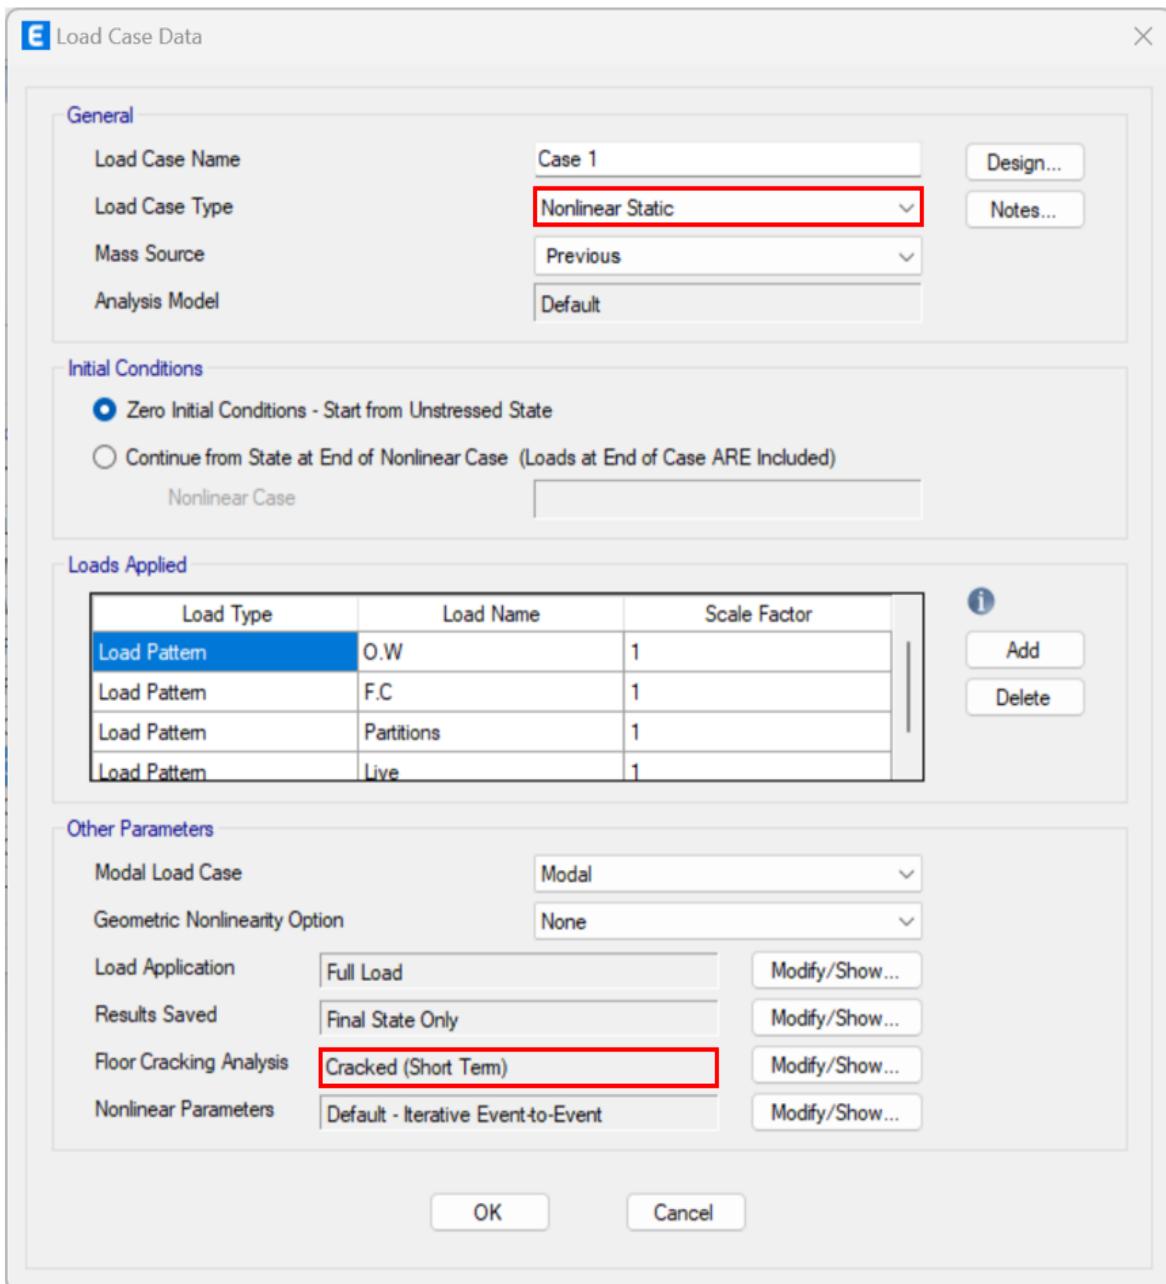

Figure 4-18 Case 1

#### 4.6.2 Case 2: Immediate sustained loads:

Figure 4-19 shows the load data for case 2.

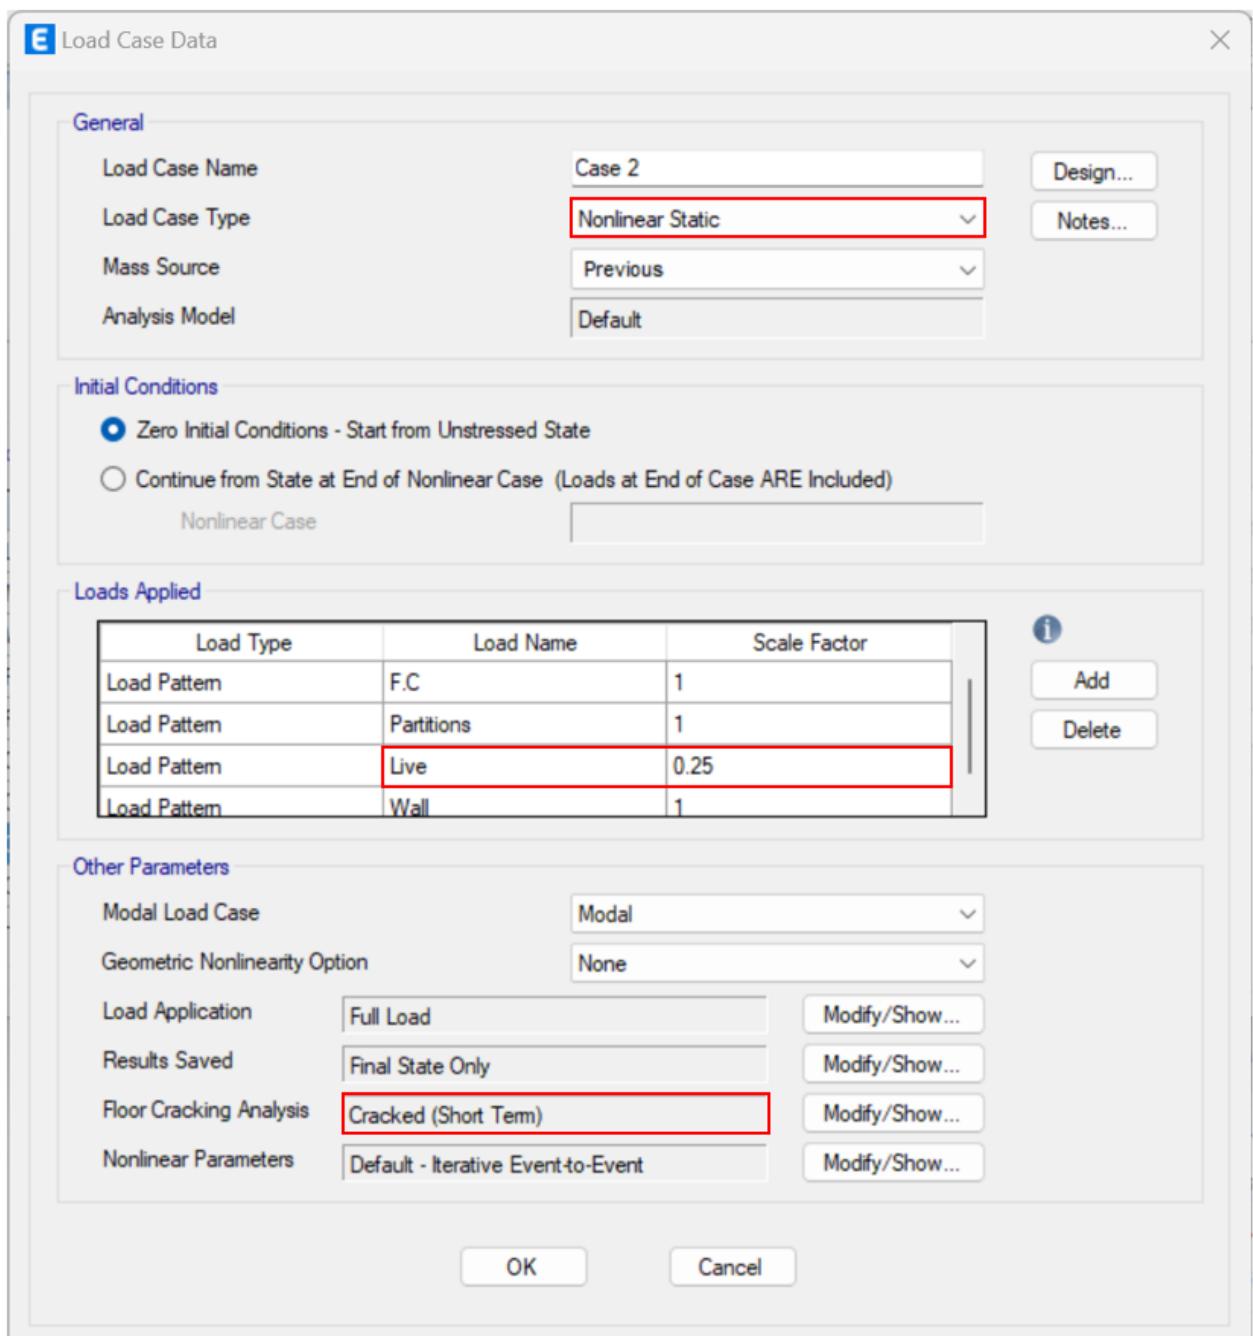

Figure 4-19 Case 2

#### 4.6.3 Case 3: Long - term sustained loads:

Figure 4-20 shows the load data for case 3.

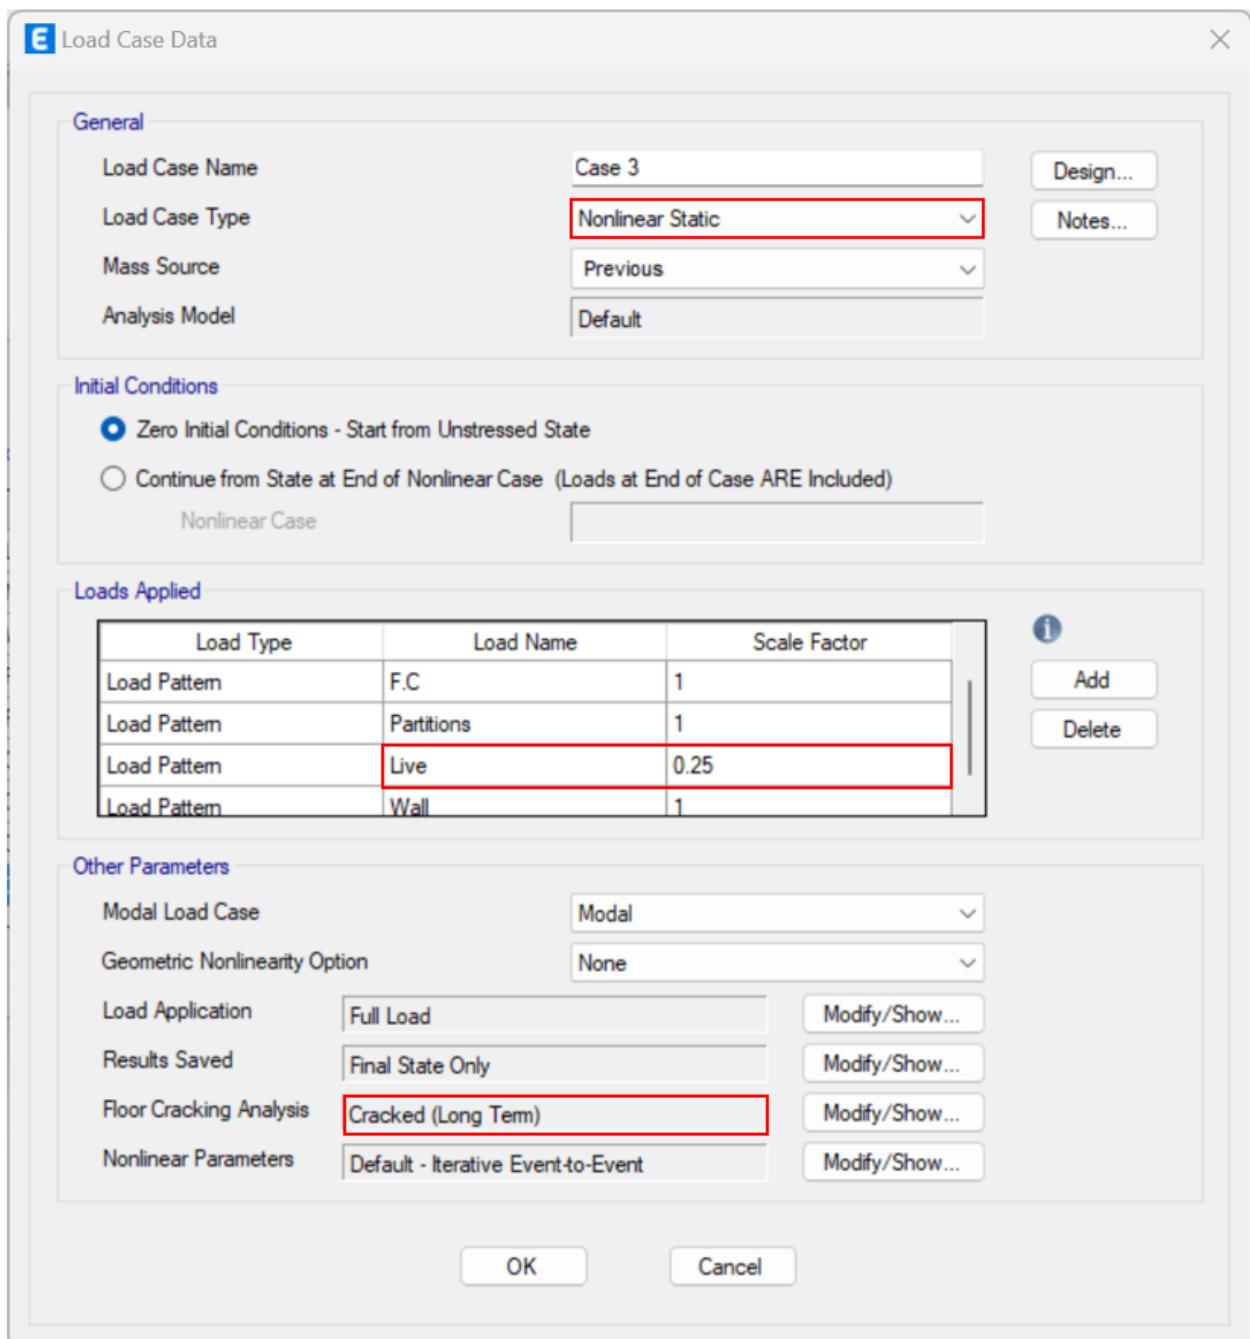

Figure 4-20 Case 3

#### **4.6.4 Load combination for long term deflection**

The load combination for long term deflection is shown in Figure 4-21.

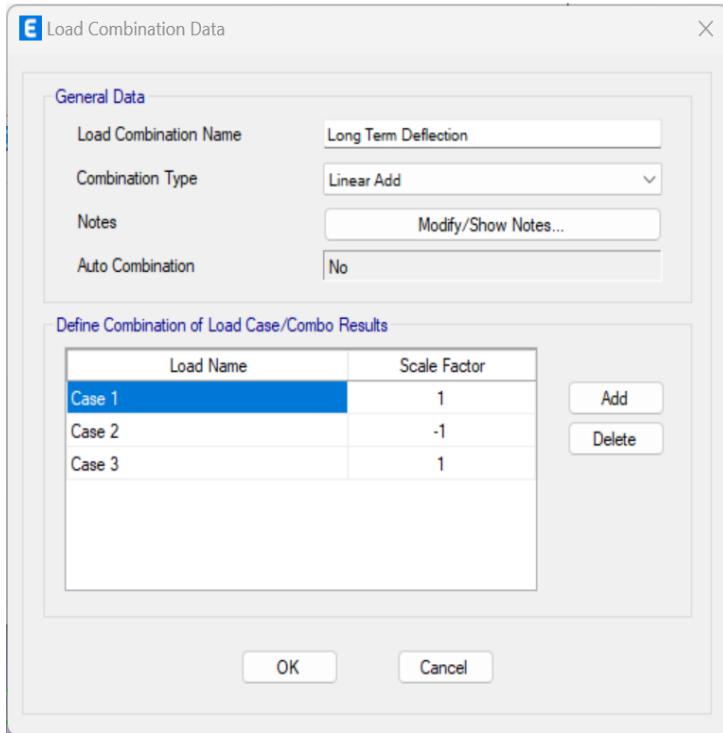

Figure 4-21 Long term deflection combination

#### **4.6.5 Check deflection limits**

Once all the load cases and combinations have been established, it is necessary to check the long-term deflection of the model to ensure that it falls within the permissible limits of deflection.

The maximum deflection calculated for flat slab is 21.315 mm as Figure 4-22 shows which is less than the allowable deflection calculated earlier 25.625 mm.

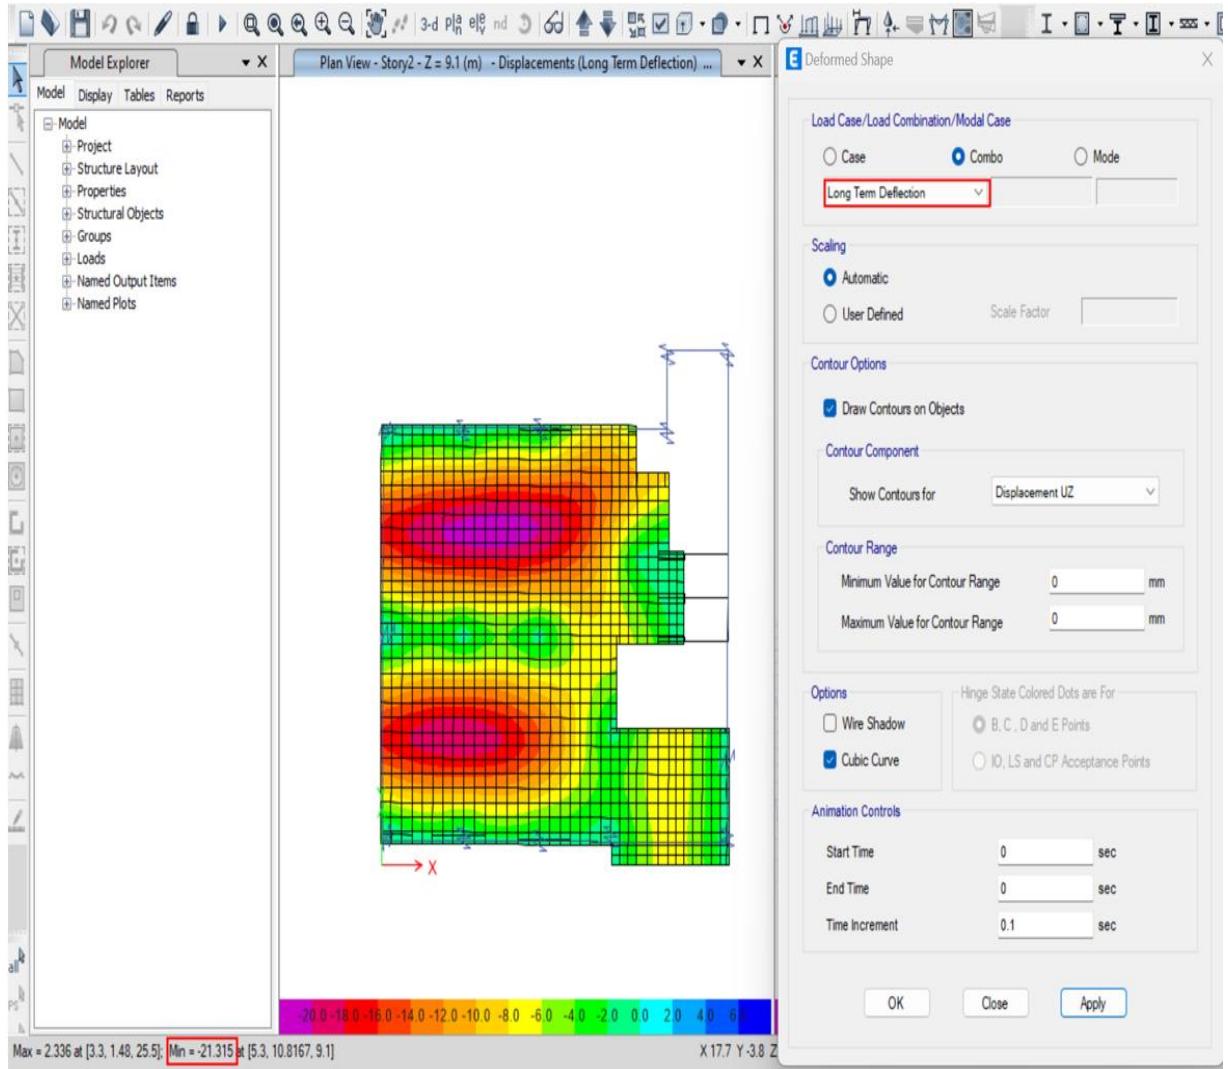

Figure 4-22 Flat slab long term deflection

The maximum deflection calculated for solid slab is 22.334 mm as Figure 4-23 shows which is less than the allowable deflection calculated earlier 25.625 mm. Thus, the long-term deflection is safe for both models according to the limit provided by SBC 304.

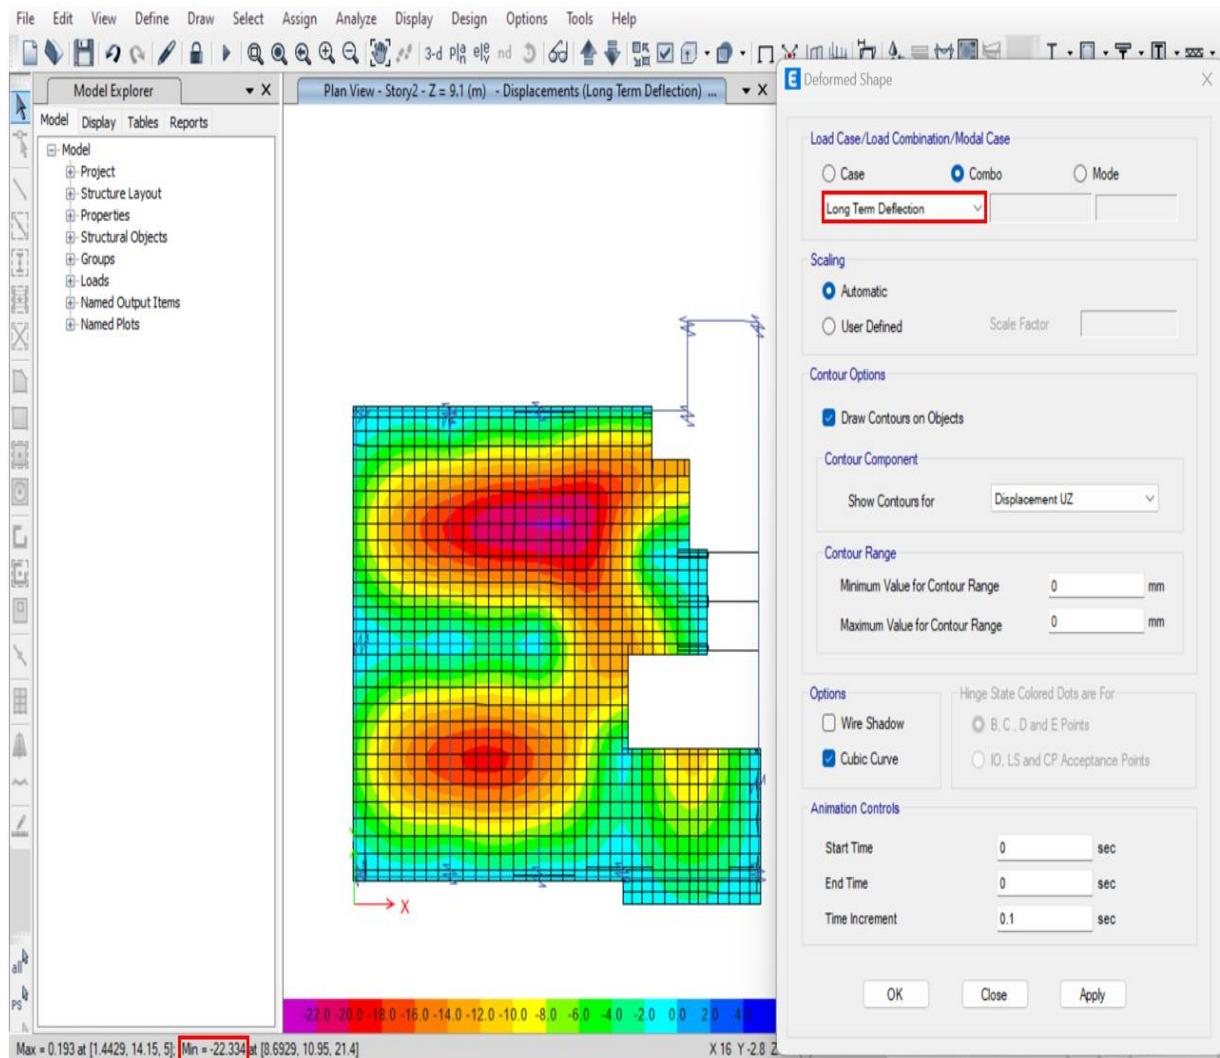

Figure 4-23 Solid slab long term deflection

## 4.7. Slab design

The finite element method was used to design the slabs, as the strip base method was not applicable due to the model not meeting its requirements. Figure 4-24 shows the finite element based in etabs.

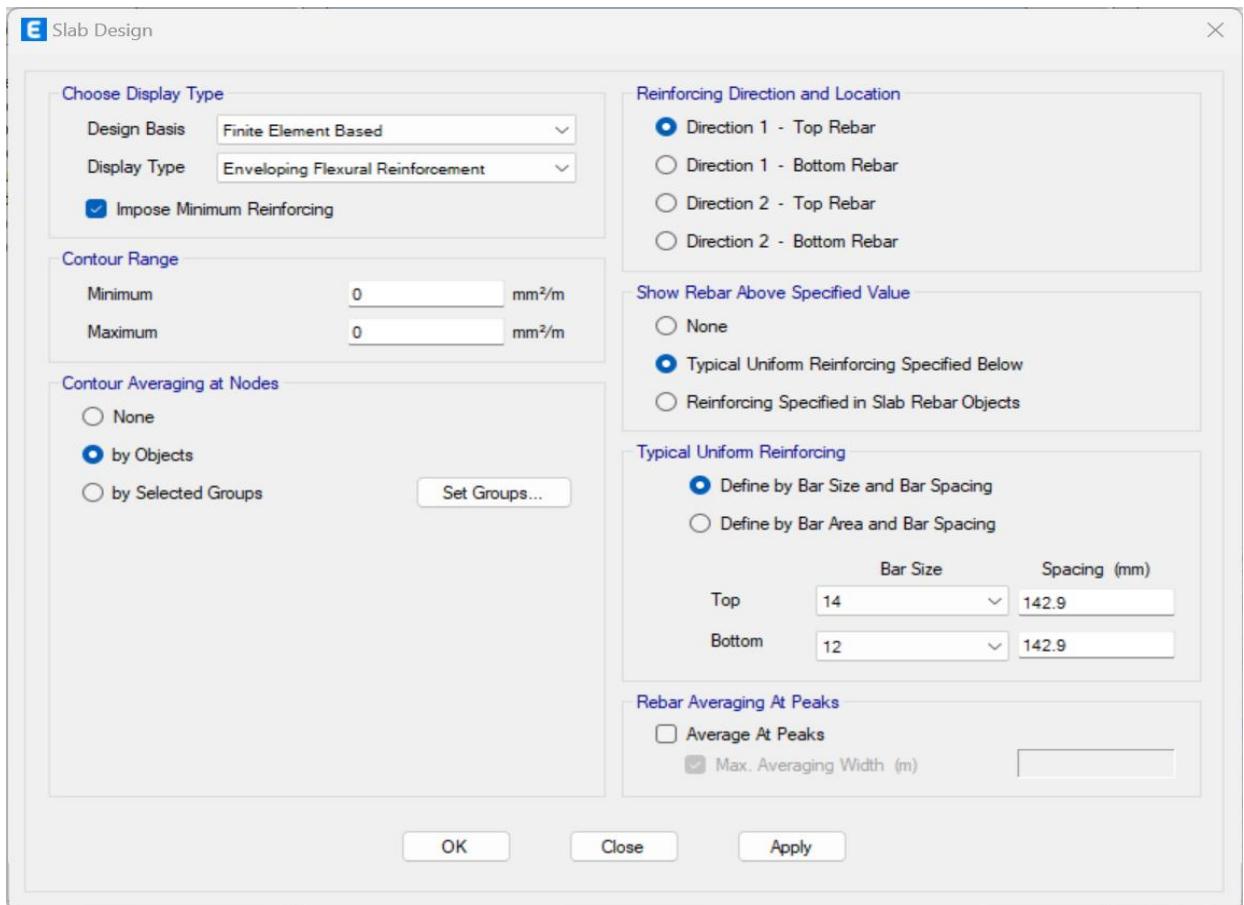

Figure 4-24 Finite element method

### 4.7.1. Flat slab design

For top reinforcement  $\Phi 14$  is selected and for bottom reinforcement  $\Phi 12$ . Figures 4-25 and 4-26 show the top reinforcement design for both directions.

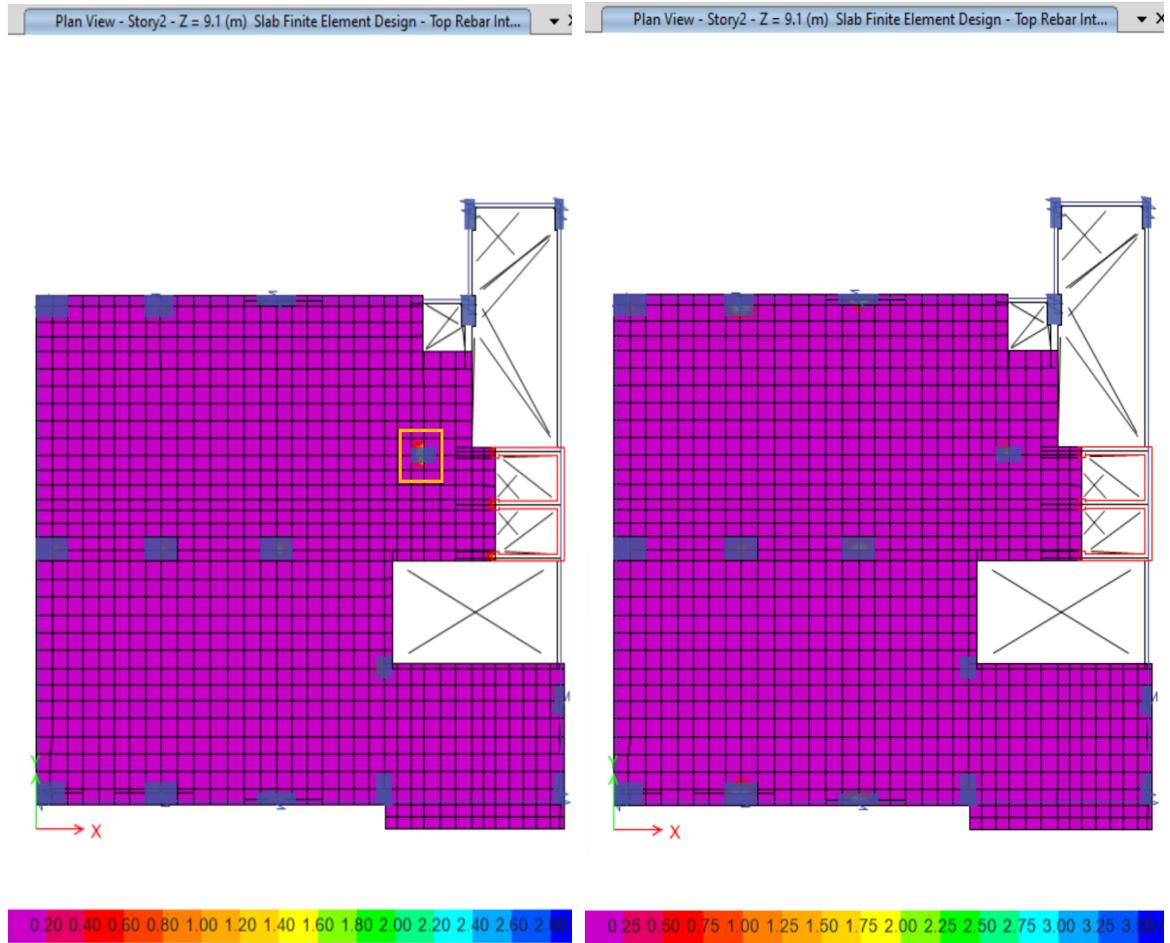

Figure 4-25 Flat slab top rebar  
direction 1

Figure 4-26 Flat slab top rebar  
direction 2

In Figure 4-25 inside the yellow box there is a red color which means it needs extra reinforcement. The value of this red color is 1400 mm<sup>2</sup>/m, so by using

$$\Phi 16: \quad n = \frac{1400}{\pi * \frac{16^2}{4}} \approx 7 \text{ bars/m}$$

Based on the analysis results, it has been determined that the top reinforcement in both directions should consist of 7 Φ14 / m, and an additional 7 Φ16 / m reinforcement is required in both directions for the area surrounding the selected column.

Figures 4-27 and 4-28 show the bottom reinforcement design for both directions. Thus, the bottom reinforcement of the flat slab for both direction is  $7 \Phi 12 / m$

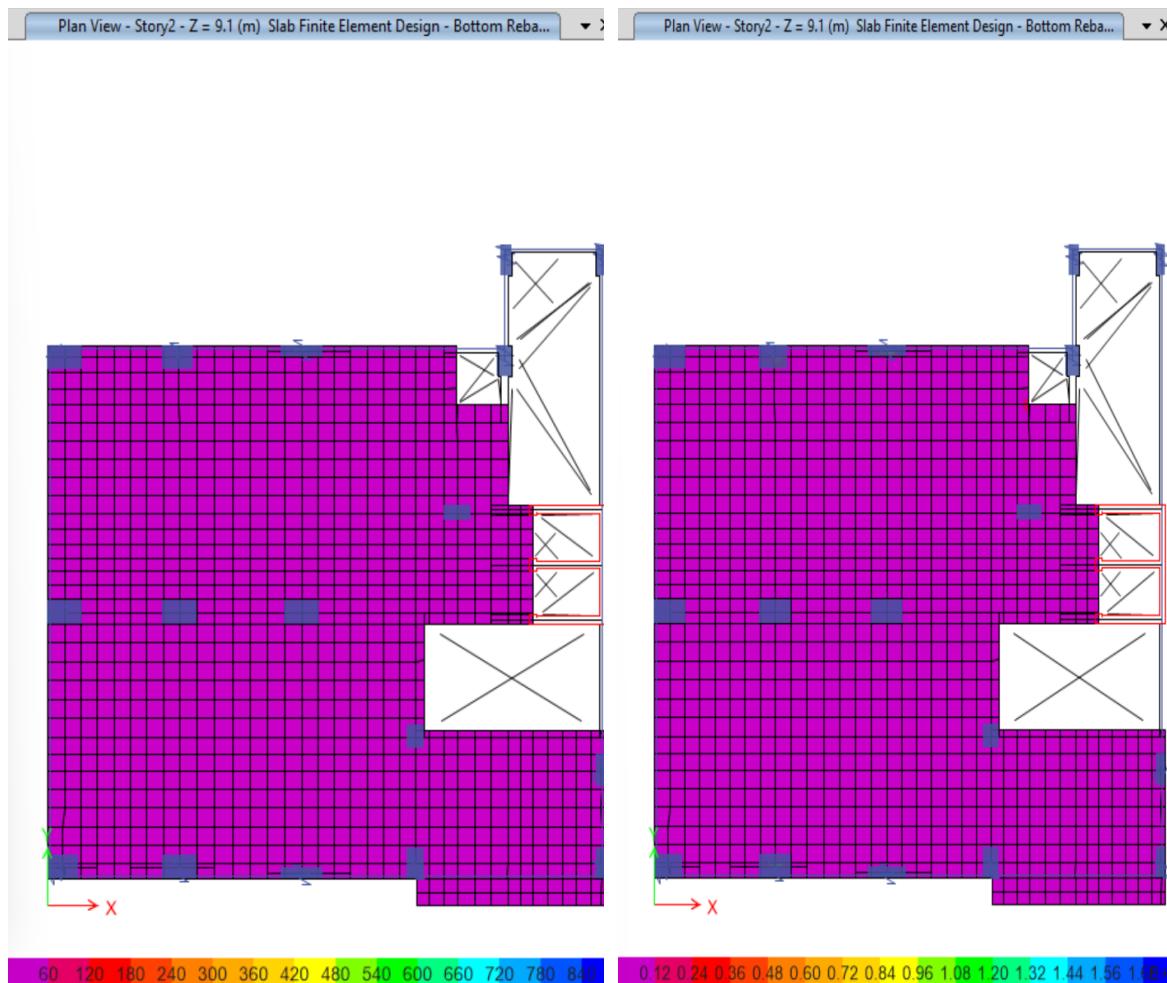

Figure 4-27 Flat slab bottom rebar  
direction 1

Figure 4-28 Flat slab bottom rebar  
direction 2

### Check of punching:

The punching shear check in ETABS is expressed as the comparison of the calculated punching shear demand to the calculated punching shear capacity of the slab, so if the value is less than 1 it means safe against punching.

Figure 4-29 shows the punching check of the flat slab.

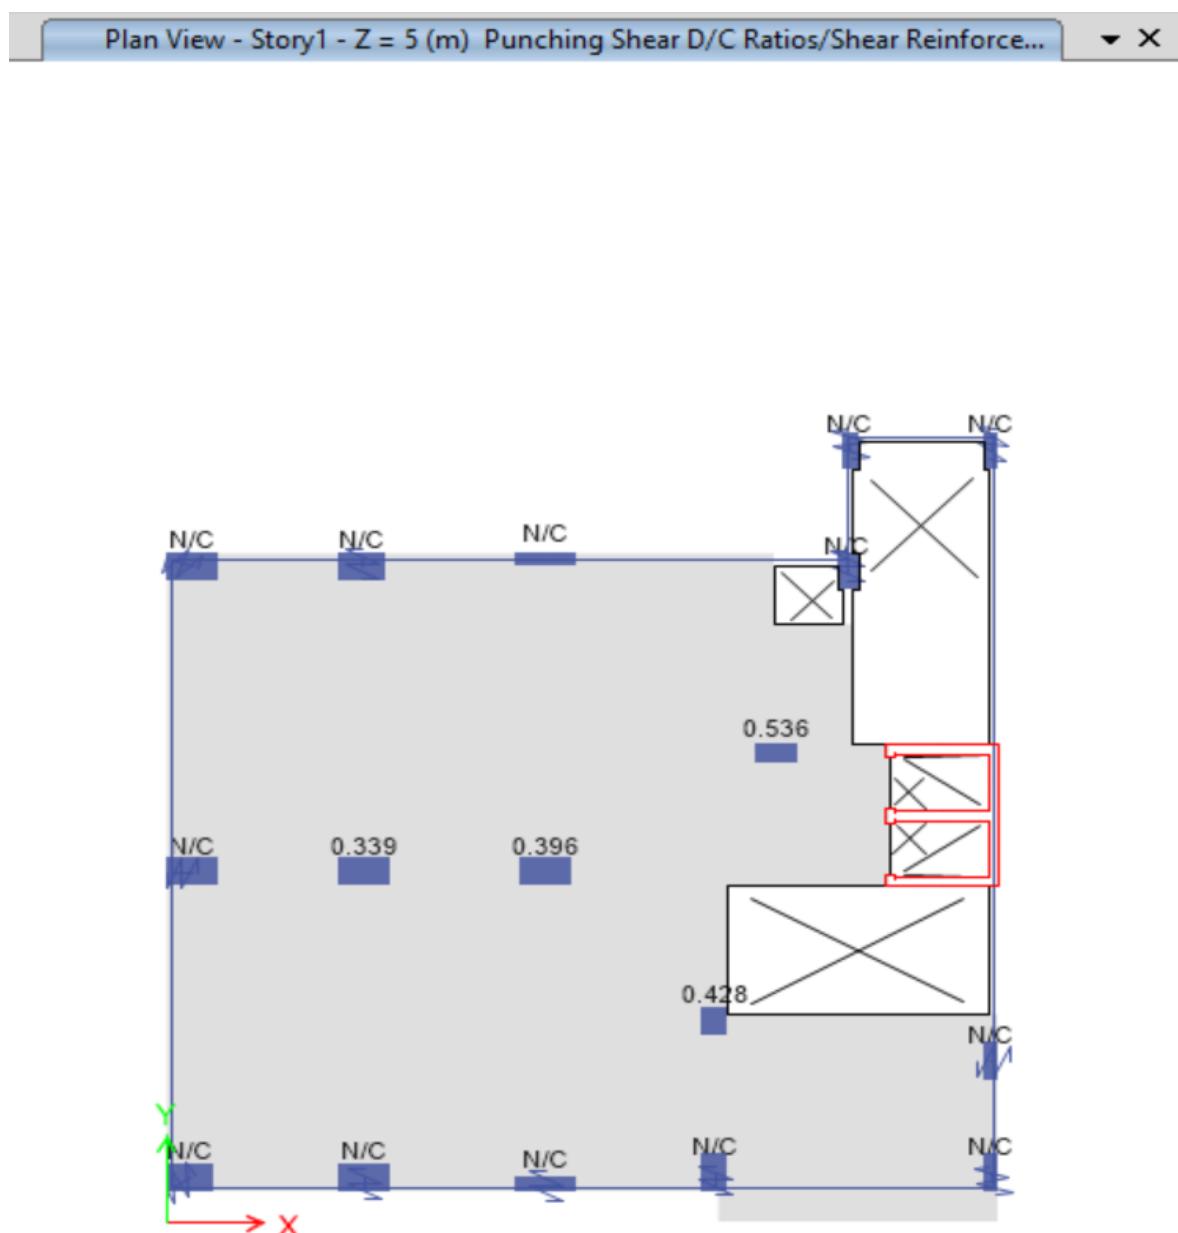

Figure 4-29 Punching Check

#### 4.7.2. Solid slab design

For top and bottom reinforcement  $5\Phi 10/\text{m}$  is selected.

Figures 4-30 and 4-31 show the top reinforcement design for both directions.

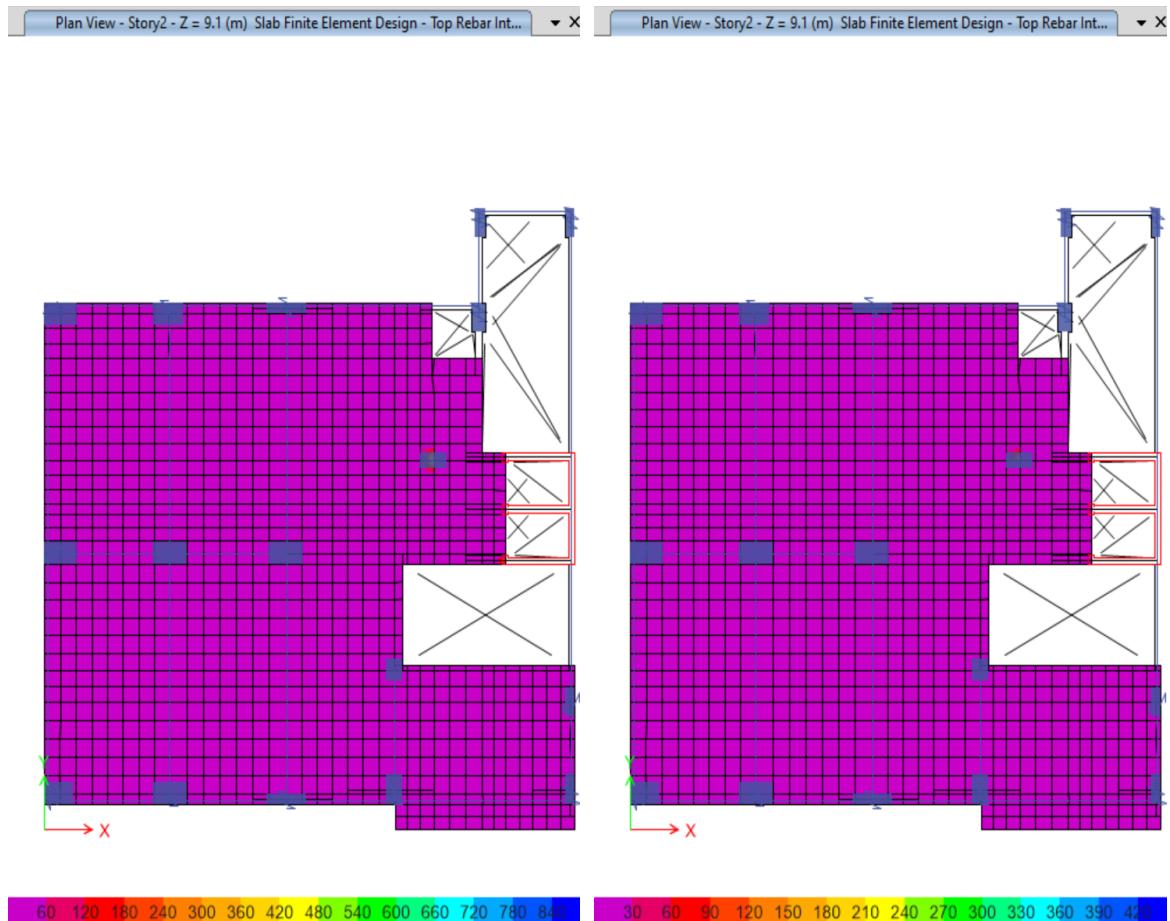

Figure 4-30 Solid slab top rebar  
direction 1

Figure 4-31 Solid slab top rebar  
direction 2

Figures 4-32 and 4-33 show the bottom reinforcement design for both directions.

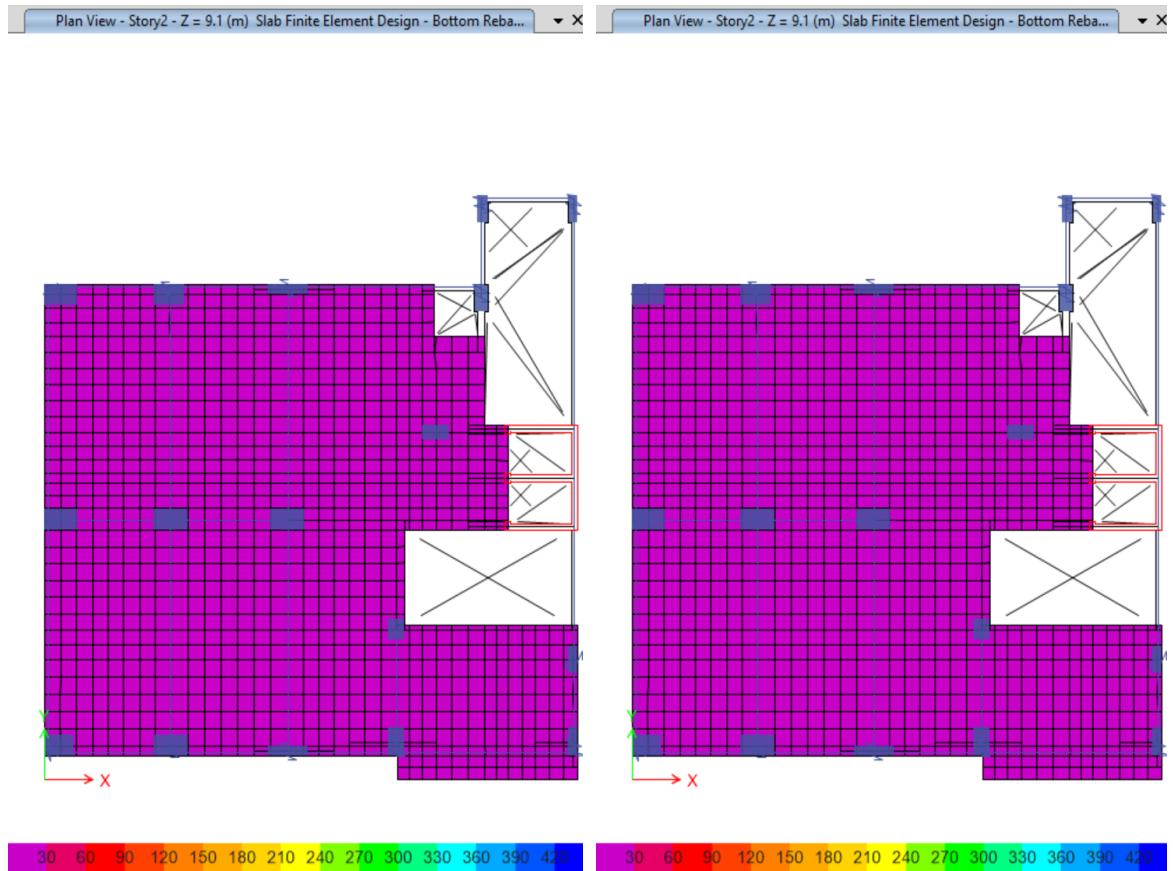

Figure 4-32 Solid slab bottom rebar  
direction 1

Figure 4-33 Solid slab bottom rebar  
direction 2

Overall, the reinforcement of the solid slab is  $5 \Phi 10 / m$  top and bottom both directions.

## 4.8. Beam design

Beam design will be done by using ETABS and checked by using Excel sheet.

### 4.8.1. Flat slab moments

The moment diagram of the beams from story 1 to 7 is calculated in ETABS as shown in figures 4-34, 4-35, 4-36, 4-37 and 4-38.

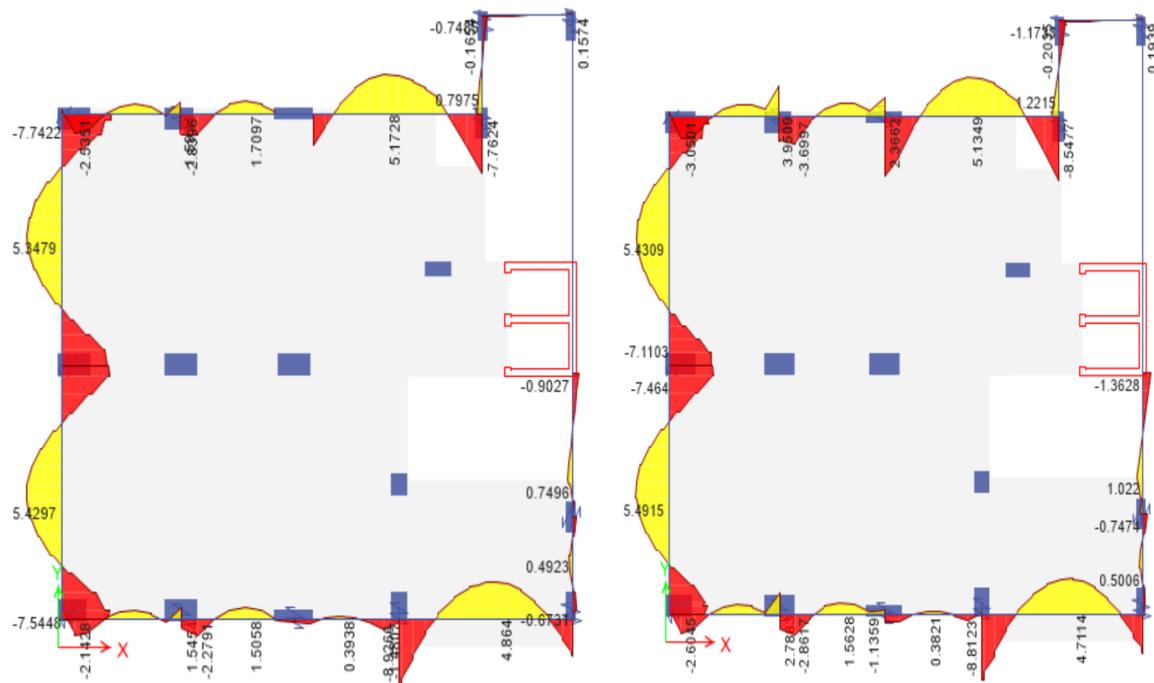

Figure 4-34 Beams moment (story 1)

Figure 4-35 Beams moment (story 2)

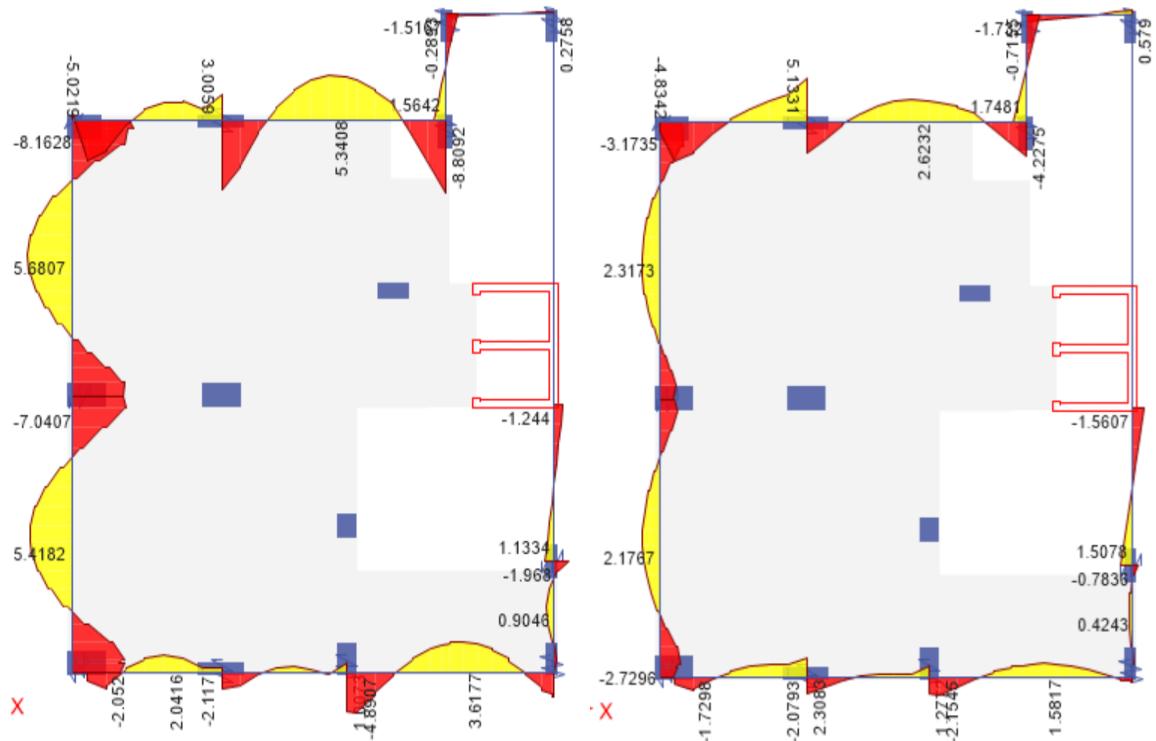

Figure 4-37 Beams moment (story 6)

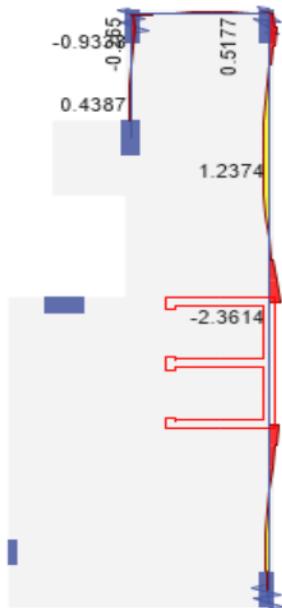

Figure 4-38 Beams moment (story 7)

#### 4.8.2. Solid slab moments

The moment diagram of the beams from story 1 to 7 is calculated in ETABS as shown in figures 4-39, 4-40, 4-41, 4-42 and 4-43.

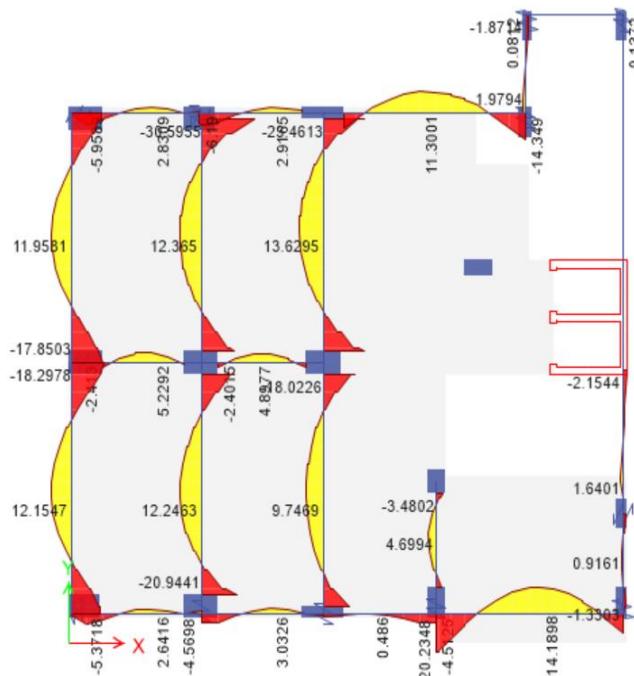

Figure 4-39 Beams moment (story 1)

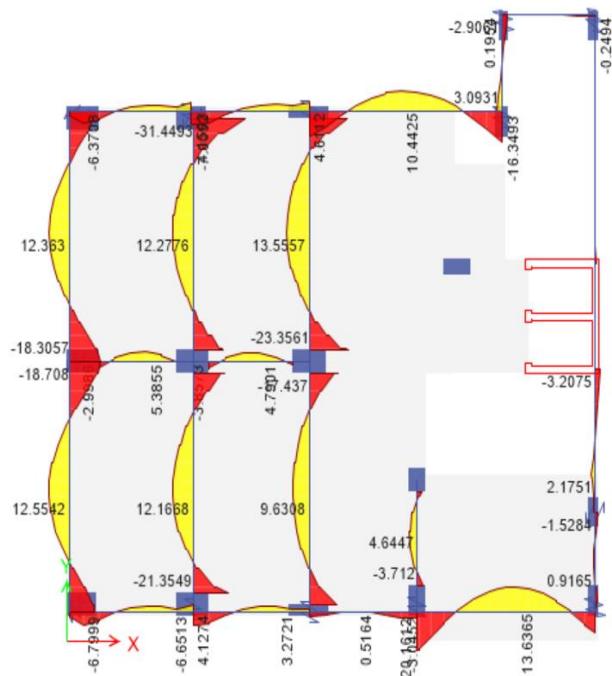

Figure 4-40 Beams moment (story 2)

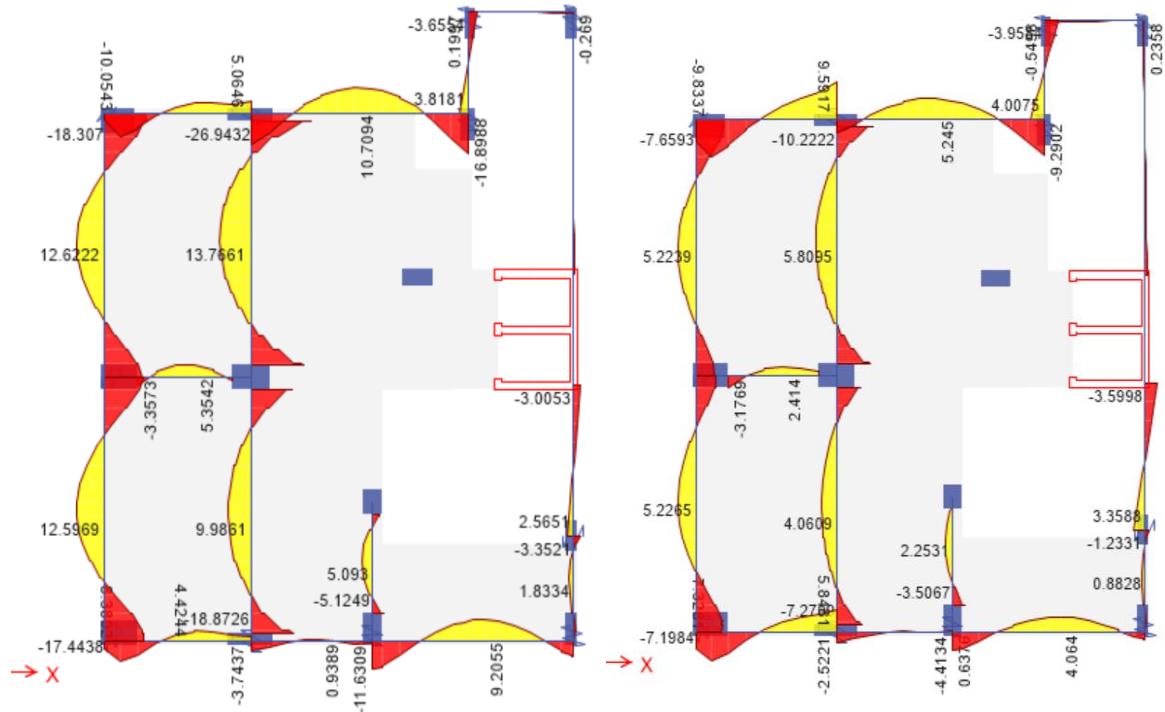

Figure 4-41 Beams moment (story 3 to 5)

Figure 4-42 Beams moment (story 6)

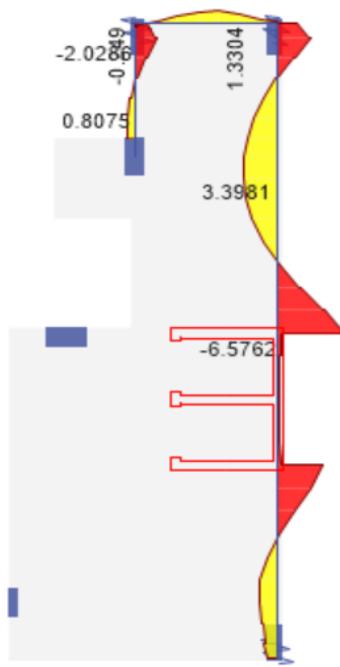

Figure 4-43 Beams moment (story 7)

#### 4.8.3. Beams reinforcement

There are three types of beams, B1 (600 \* 300) mm, B2 (600 \* 300) mm for flat slab and B3 (400 \* 200) mm for solid slab. By taking the maximum moment on B1, B2 and B3 and calculating for reinforcement it was found that all the beams are designed for minimum reinforcement as shown in Table 4-1.

Table 4-1 Beam design

Section #	Mu (KN.m)	Dimensions			Required As (mm^2)	Min As (mm^2)	As (mm^2)	a (mm)	φMn (KN.m)	Reinforcement	
		b (mm)	h (mm)	d (mm)						No. Bar	φ (mm)
B1	9	300	600	540	44.2	540	540	35.58	106.6	3	16
B2	10	200	600	540	49.1	360	360	35.58	71.06	2	16
B3	28	200	400	340	225.2	226.7	226.7	22.40	28.17	2	16

Beam design equations [5]:

$$A_s = \frac{0.85 \times f'_c \times b \times d}{f_y} \times \left( 1 - \sqrt{1 - \frac{4 \times M_u}{0.9 \times 1.7 \times f_c \times b \times d^2}} \right) \quad (4-2)$$

$$a = \frac{A_s \times f_y}{0.85 \times f'_c \times b} \quad (4-3)$$

$$\Phi M_n = A_s \times f_y \times \left( d - \frac{a}{2} \right) \quad (4-4)$$

Where Φ here is equal to (0.9).

By designing the beams with etabs also gives the same reinforcement area as shown in figures 4-44 and 4-45.

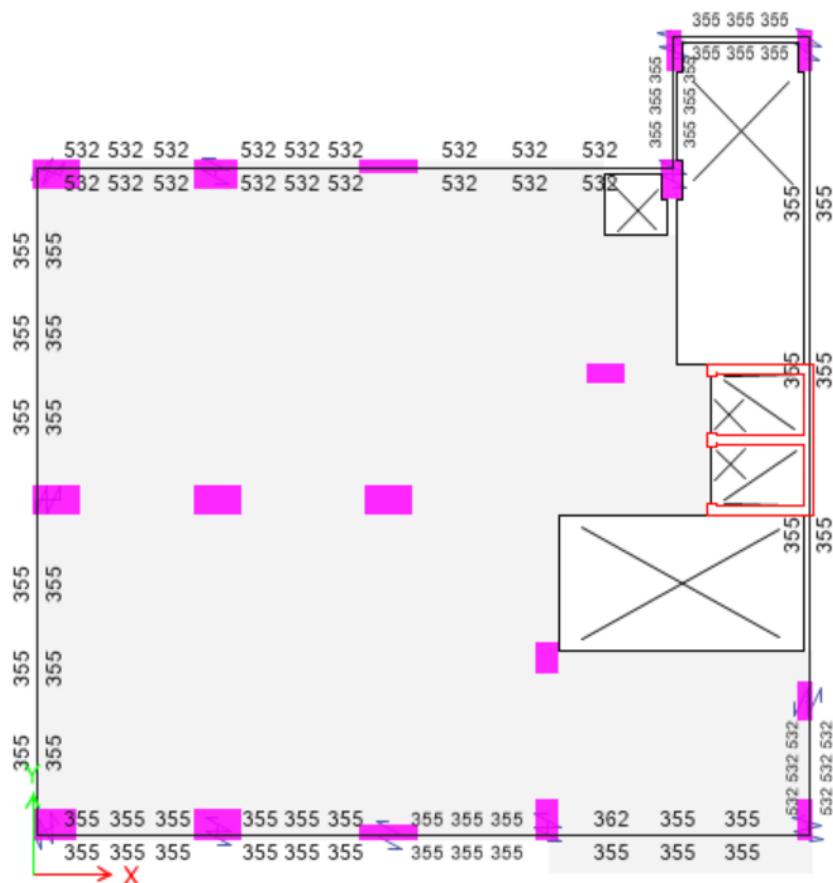

Figure 4-44 Beam longitudinal rebars (flat slab)

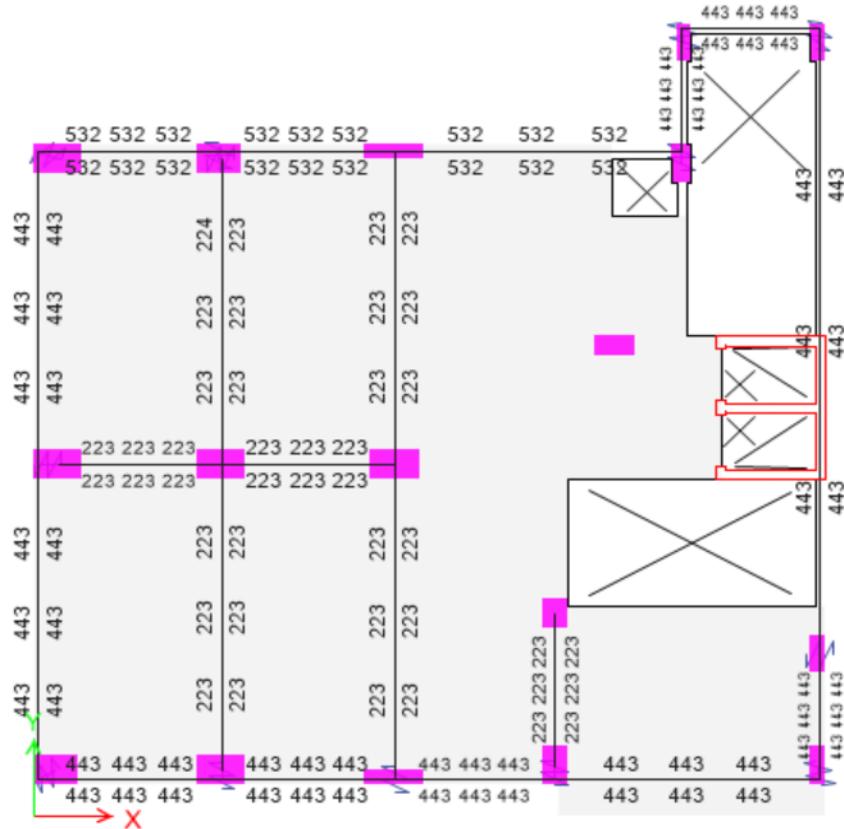

Figure 4-45 Beam longitudinal rebars (solid slab)

#### 4.8.4. Shear reinforcement

It should be noted that the shear reinforcement is not required for B1 and B2 beams in solid slab system as shown in figures 4-46 and 4-47 according to SBC 304 [1] (9.6.3.1 “ $A_{v,min}$  shall be provided in all region where  $V_u > 0.5 * \phi V_c$ ”). However, omitting stirrups in beam can have several potential consequences such as (reducing ductility, cracking, and increasing deflection). Figure 4-48 displays the output obtained from Etabs software concerning the shear force and reinforcement for beam in flat slab system. To determine the spacing of stirrups, an 8mm diameter stirrup shall be considered first, and then check code limitations.

**Shear Force and Reinforcement for Shear,  $V_{u2}$**

<b>Shear <math>V_{u2}</math> kN</b>	<b>Shear <math>\phi V_c</math> kN</b>	<b>Shear <math>\phi V_s</math> kN</b>	<b>Shear <math>V_p</math> kN</b>	<b>Rebar <math>A_v/s</math> <math>\text{mm}^2/\text{m}</math></b>
13.4086	47.9753	0	0	0

Figure 4-46 Shear reinforcement of B1beam (Solid)

**Shear Force and Reinforcement for Shear,  $V_{u2}$**

<b>Shear <math>V_{u2}</math> kN</b>	<b>Shear <math>\phi V_c</math> kN</b>	<b>Shear <math>\phi V_s</math> kN</b>	<b>Shear <math>V_p</math> kN</b>	<b>Rebar <math>A_v/s</math> <math>\text{mm}^2/\text{m}</math></b>
3.3822	39.9794	0	0	0

Figure 4-47 Shear reinforcement of B2 beam (Solid)

Figure 4-48 Shear reinforcement results from Etabs (Flat)

- Required shear steel area results from Etabs is  $A_v/s = 250 \text{ mm}^2/\text{m}$
- Area of two legs 8mm diameter stirrup is  $A_v = 2 * \frac{\pi * 8^2}{4} = 100.5 \text{ mm}^2$
- Required Spacing is  $s = \frac{100.5}{250} = 0.402 \text{ m}$

However, according to SBC 304 [1]; maximum spacing of shear reinforcement shall be minimum of ( $d/2$  or 600 mm) so,  $s=270\text{mm}$ . Therefore, take the transverse reinforcement of all beams for both structural systems as ( $\Phi 8\text{mm}$  @ 25 cm).

#### 4.9. Column design

The loads on the columns are found by using ETABS axial force as shown in Figure 4-49.

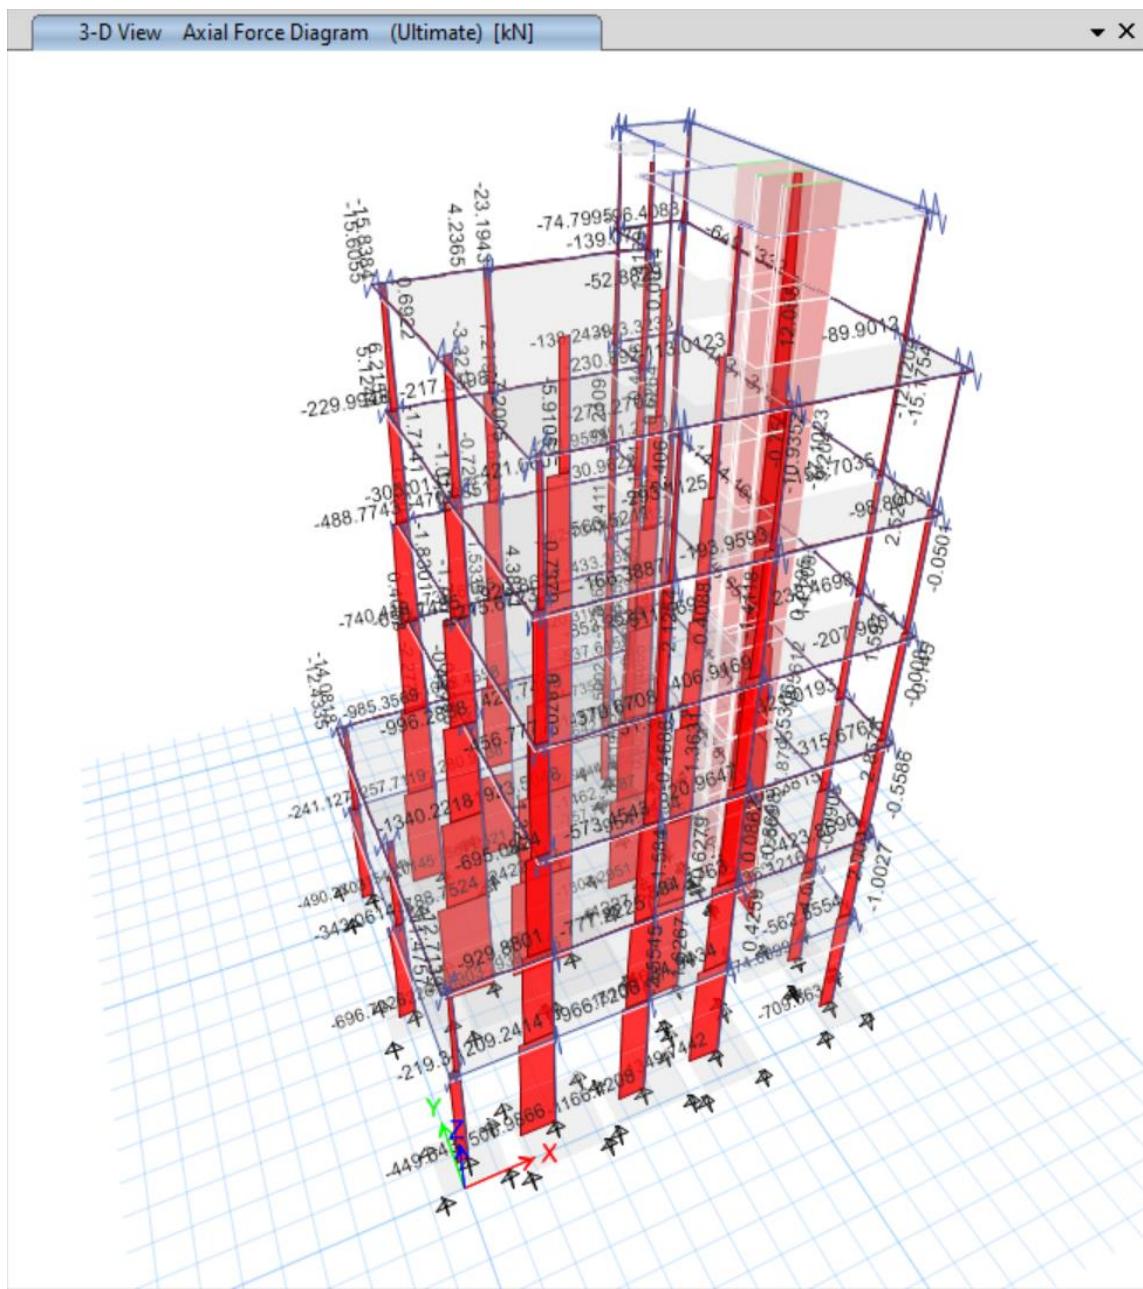

Figure 4-49 Columns axial force

By taking the axial loads on the columns it was found that all the columns are design on the minimum reinforcement as Table 4-2 below shows.

Table 4-2 Column design

Col #	Pu (KN)	Dimensions		Ag (mm <sup>2</sup> )	Min As (mm <sup>2</sup> )	Required As (mm <sup>2</sup> )	As (mm <sup>2</sup> )	φPn (KN)	Reinforcement

Where the area steel is found using eq (4-5) [1]:

$$\Phi P_n = 0.8 \times 0.65 \times (0.85 \times f'_c \times (A_g - A_s) + f_y \times A_s) \quad (4-5)$$

where  $\Phi P_n \geq P_u$

And area steel minimum according to SBC 304 is 1% of the area gross.

#### 4.10. Shear wall design

Shear walls serve as the selected resisting system for lateral forces, including wind and seismic loads. The placement of shear walls on the blueprint as shown in Figure 4-50 was strategically implemented to avoid torsion in the building. This was achieved by ensuring that the center of mass and rigidity were positioned close.

This section of the report presents the design requirements, equations, and final reinforcement area obtained from ETABS software for designing shear

walls. The analysis and design process consider factors, such as structural integrity, material properties, and SBC provisions. Additionally, Figure 4-51 shows a flowchart outlined the step-by-step process for the structural design of shear walls.

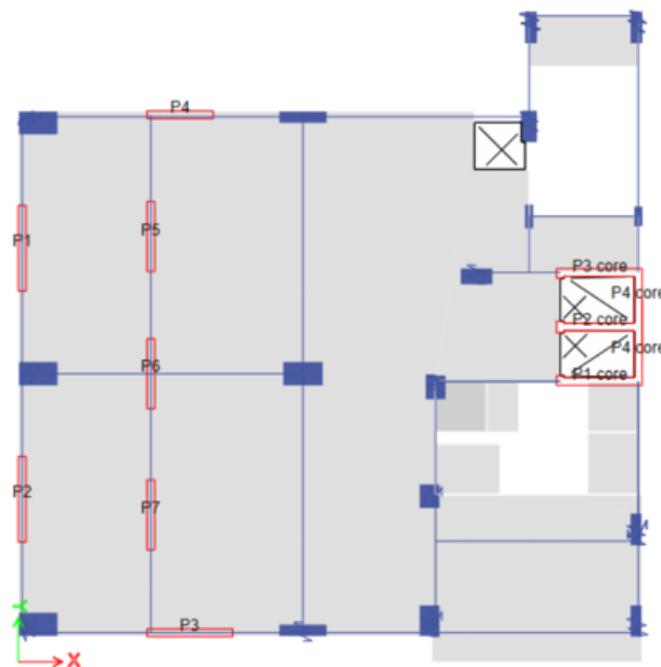

Figure 4-50 The blueprint of the building showing added shear walls

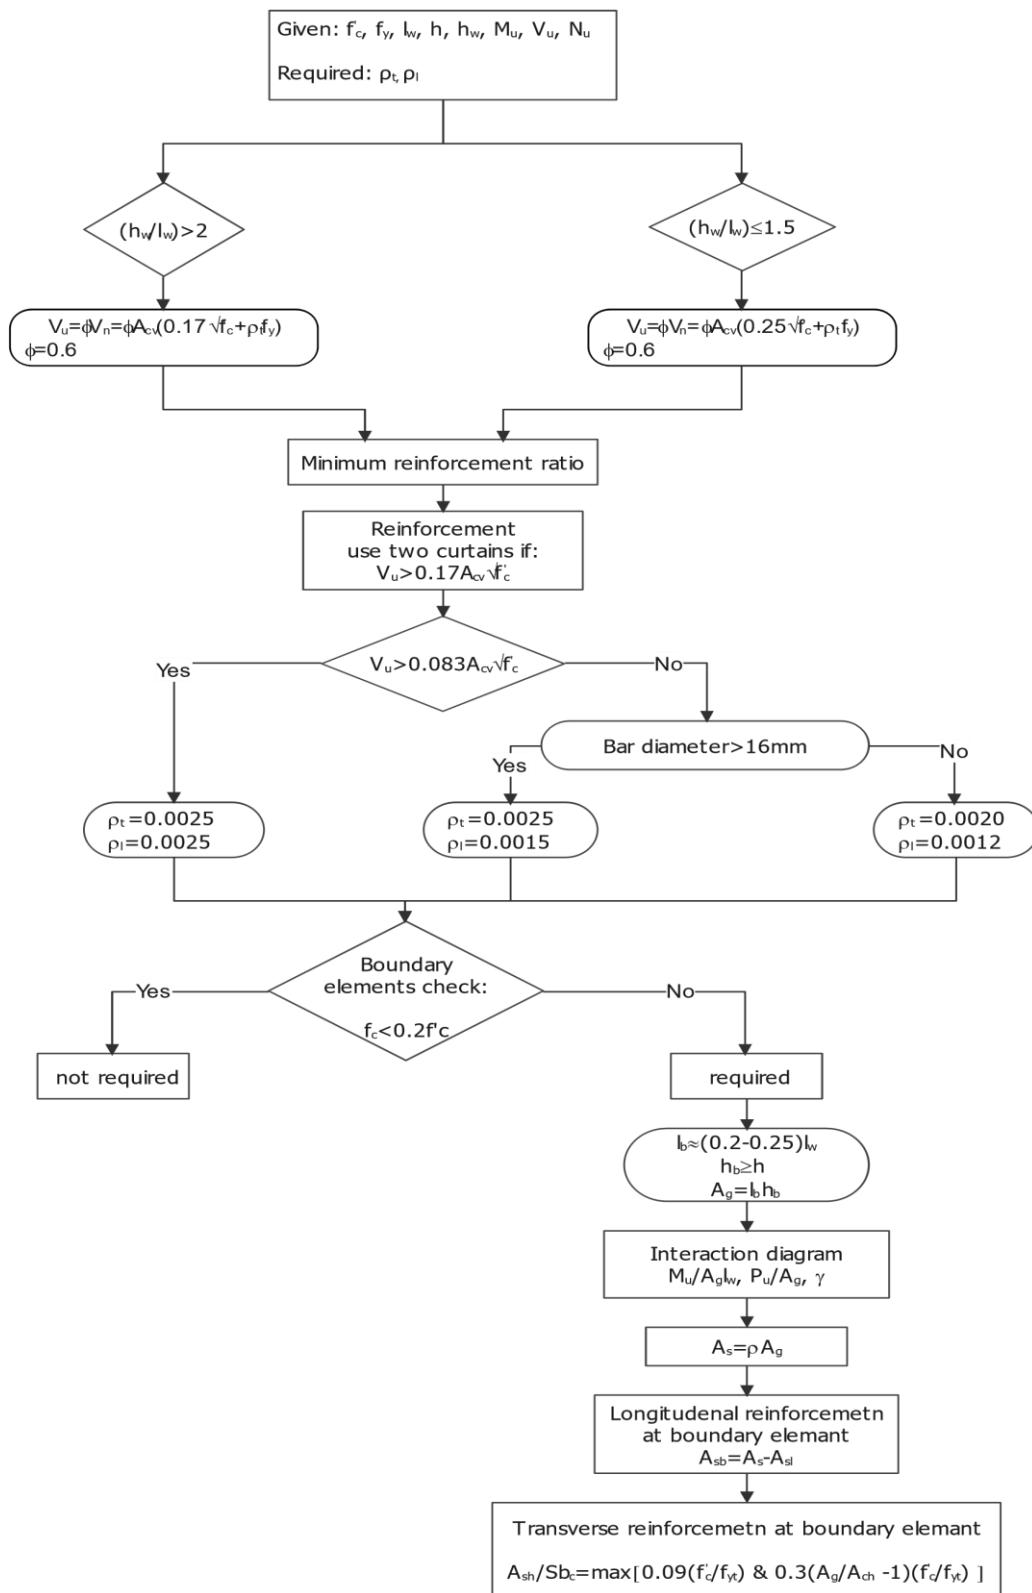

Figure 4-51 The design flowchart for a shear wall

#### 4.10.1. Design requirements and equations

❖ Shear strength [1]:

$$V_C = 0.17 \times \lambda \times \sqrt{f'_c} \times h \times d \quad (4-6)$$

$$V_S = \frac{V_u}{\phi} - V_C \quad (4-7)$$

$$A_v = \frac{V_S \times S}{f_{yt} \times d} \geq A_{v \min} = \rho_t \times h \times S \quad (4-8)$$

$$V_{S \ min} = \frac{A_v \times f_{yt} \times d}{S} \quad (4-9)$$

$$V_n = V_C + V_S \quad (4-10)$$

Where:

$V_C$ : Nominal shear strength provided by concrete (N).

$V_S$ : Nominal shear strength provided by shear reinforcement (N).

$V_n$ : Nominal shear strength (N).

$\lambda$ : Modification factor to reflect the reduced mechanical properties of lightweight concrete.

$h$ : Overall thickness of the member (mm).

$d$ : Distance from extreme compression fiber to centroid of longitudinal tension reinforcement (mm).

$V_u$ : Factored shear force at section (N).

$S$ : Center to center spacing of items (mm).

$A_v$ : Area of shear reinforcement within spacing ( $\text{mm}^2$ ).

$f'_c$ : Specified compressive strength of concrete (MPa).

$f_{yt}$ : Specified yield strength of transverse reinforcement (Mpa).

#### 4.10.2. Reinforcement area

The chosen design approach in ETABS was the Uniform Reinforcing method, which involves the inclusion of reinforcement area in both the longitudinal and transverse directions across the section of the wall, while also ensuring compliance with the necessary boundary element requirements, as shown in figures 4-52, 4-53, 4-54, and 4-55. The reinforcement areas for each wall obtained from ETABS were documented in Table 4-3 further detailed in the Drawings section using Revit software.

## CHAPTER 5. FOUNDATIONS

### 5.1. Isolated Footing:

An isolated footing is a type of foundation that is used to support a single column or a small group of columns. It is typically a rectangular or circular slab of concrete that is reinforced with steel bars and placed directly on the soil. The purpose of the footing is to spread the load of the structure over a larger area of soil in order to prevent excessive settlement or bearing capacity failure. The design of an isolated footing involves determining the size and thickness of the footing, as well as the amount and placement of the reinforcing steel. Figure 5-1 below shows a simple isolated footing.

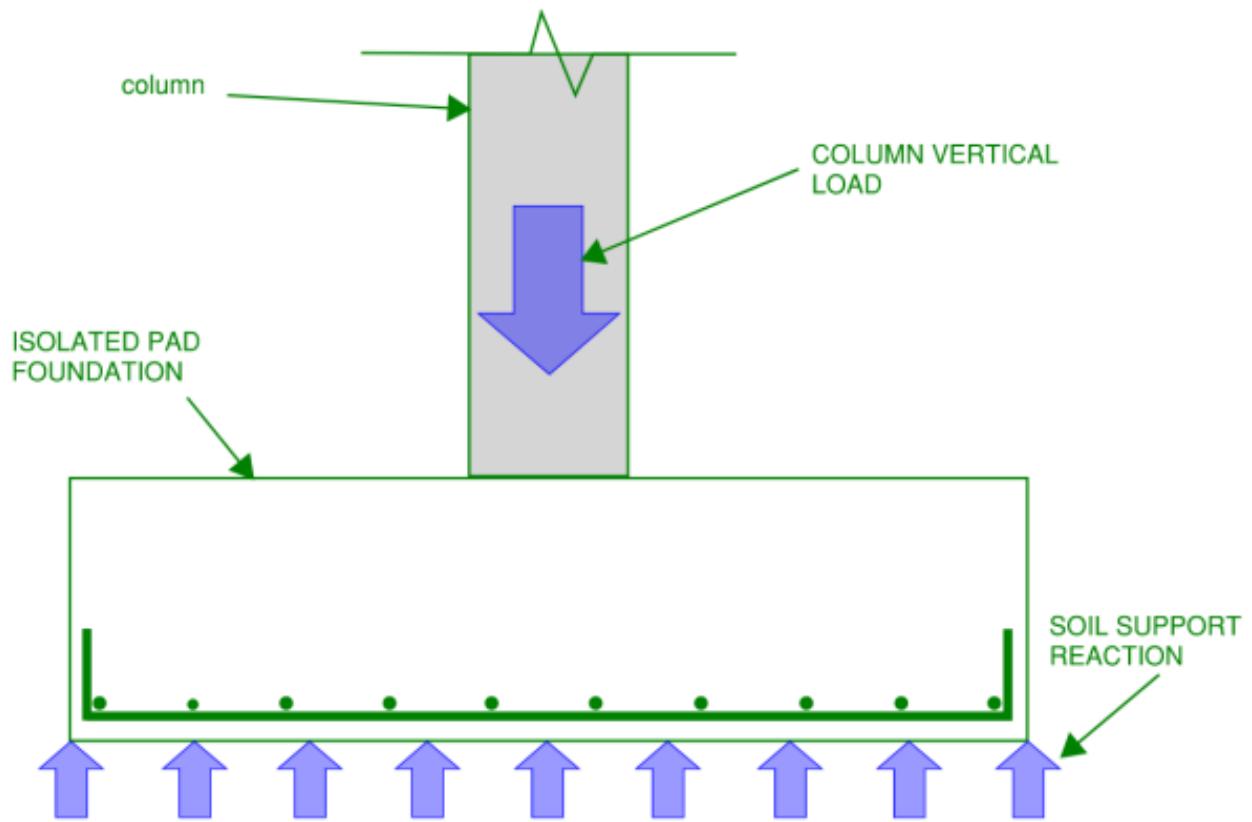

Figure 5-1 Isolated footing

### 5.1.1. Assumptions

Since there is no geotechnical report available the following assumptions were made:

- ❖ Concrete compressive strength  $f_c = 25 \text{ MPa}$
- ❖ Steel tensile strength  $f_y = 420 \text{ MPa}$
- ❖ Soil unit weight  $\gamma_{\text{soil}} = 15 \text{ kN/m}^3$
- ❖ Soil bearing capacity  $q_{\text{all}} = 200 \text{ kN/m}^2$
- ❖ Unit weight of concrete  $\gamma_{\text{concrete}} = 25 \text{ kN/m}^3$
- ❖ Distance from the surface to the top of footing  $D_f = 1.2 \text{ m}$
- ❖ Minimum thickness  $t_{\min} = 0.5 \text{ m}$

### 5.1.2. Formulas

The design of an isolated footing involves several steps including determining the required size and thickness of the footing, calculating the loads that the footing will be subjected to, and selecting the appropriate reinforcing steel [4].

$$A_f = \frac{Q_{Working}}{q_{all\ net}} \quad (5-1)$$

$$q_{all\ net} = q_{all} - (\gamma_s \times D_f + \gamma_c \times t_f) \quad (5-2)$$

$$q_s = \frac{Q_{ult}}{A_f} \quad (5-3)$$

Where:

$A_f$ : Area of the foundation ( $m^2$ ).

$Q_{Working}$ : The load of the column (kN).

$q_{all\ net}$ : The net allowable gross soil bearing capacity ( $kN/m^2$ ).

$q_{all}$ : Soil bearing capacity ( $kN/m^2$ ).

$\gamma_s$ : Soil unit weight ( $kN/m^3$ ).

$D_f$ : Distance from the surface to the top of footing (m)

$\gamma_c$ : Unit weight of concrete ( $kN/m^3$ ).

$t_f$ : footing thickness (m).

$q_s$ : The Contact Soil Bearing Capacity ( $kN/m^2$ ).

$Q_{ult}$ : The ultimate load of the column (kN).

### Foundation shear Strength:

❖ For one way shear ( $V_u \leq \Phi V_c$ ):

$$V_u = q_s \times L_f \times X \quad (5-4)$$

$$\Phi V_c = 0.75 \times 0.17 \times \sqrt{f'_c} \times B_f \times d \quad (5-5)$$

Where:

$V_u$ : shear force due to factored load (kN).

$\Phi V_c$ : design shear strength of concrete (compressive strength of concrete  $\Phi = 0.75$ ).

$X = (B - 2d - \text{Column width})/2$  (m).

$L_f$ : Length of the footing (m).

$B_f$ : Width of the footing (m).

If  $(V_u \leq \Phi V_c)$  ok continue to two-way shear.

❖ For two-way shear ( $V_u \leq \Phi V_c$ ):

$$V_u = q_s \times [(B_f \times L_f) - ((b_c + d) \times (h_c + d))] \quad (5-6)$$

$$\Phi V_c = 0.75 \times 0.34 \times \sqrt{f'_c} \times b_o \times d \quad (5-7)$$

Where:

$b_c$ : Width of the column (m).

$h_c$ : Height of the column (m).

$b_o = 2 [(b_c + d) + (h_c + d)]$ .

## Flexural reinforcement:

### ❖ Along the width direction

$$M_u = q_s \times L_f \times \frac{L'^2}{2} \quad (5-8)$$

$$a = \frac{A_s \times f_y}{0.85 \times f'_c \times L_f} \quad (5-9)$$

Where:

$$L' = (B_f - b_c)/2 \text{ (m).}$$

a: The height of the stress block (m).

Let  $M_u = \Phi \times A_s \times f_y \times (d - a/2)$ , then find  $A_{s1}$  and  $A_{s2}$ .

$\rho = [A_s / (B \times d)]$ , (check  $\rho_{\min} < \rho < \rho_{\max}$ ) then select  $A_s$

$$n = \frac{A_s}{\pi \times \frac{d_b^2}{4}} \quad (5-10)$$

Where:  $\rho_{\min} = 0.0018$  and  $\rho_{\max} = 0.75 \times \left( \frac{0.85 \times f'_c \times B_f \times 600}{f_y \times (600 + f_y)} \right)$ .

### ❖ Along the length direction

$$M_u = q_s \times B_f \times \frac{B'^2}{2} \quad (5-8)$$

$$a = \frac{A_s \times f_y}{0.85 \times f'_c \times B_f} \quad (5-9)$$

Where:

$$B' = (L_f - h_c)/2 \text{ (m).}$$

Let  $M_u = \Phi \times A_s \times f_y \times (d - a/2)$ , then find  $A_{s1}$  and  $A_{s2}$ .

$\rho = [A_s / (B \times d)]$ , (check  $\rho_{min} < \rho < \rho_{max}$ ) then select  $A_s$

$$n = \frac{A_s}{\pi \times \frac{d_b^2}{4}} \quad (5-10)$$

### Check Development Length:

The development length of the reinforcing bars in an isolated footing is an important aspect of the design, as it ensures that the bars are properly anchored in the concrete and can resist the applied loads.

$$L_d = \max \left[ \left( 0.019 \times A_{bar} \times \frac{f_y}{\sqrt{f'_c}} \right), (0.058 \times d_b \times f_y) \right] \quad (5-11)$$

$$L_{dav} = \frac{B}{2} - \frac{b_c}{2} - cc \quad (5-12)$$

Check if  $L_{dav} > L_d$  (ok) otherwise increase B.

#### 5.1.3. Design by EXCEL:

The formulas listed in 5.1.2. have been entered into excel to create a model for designing isolated footing. Tables 5-1, 5-2, 5-3, 5-4, 5-5, 5-6 and 5-7 show an example of the designed footing in excel.

Table 5-1 Inputs

## 5.2. Strip footing

A strip footing, also known as a continuous footing or a wall footing, is a type of shallow foundation used to distribute the load of a building or structure to the underlying soil. It consists of a continuous strip of concrete or masonry that extends along the length of a load-bearing wall or column. Strip footings are typically wider than the wall they support and are designed to transfer the vertical loads to the soil while also providing stability against lateral movements. Figure 5-4 shows the strip footing.

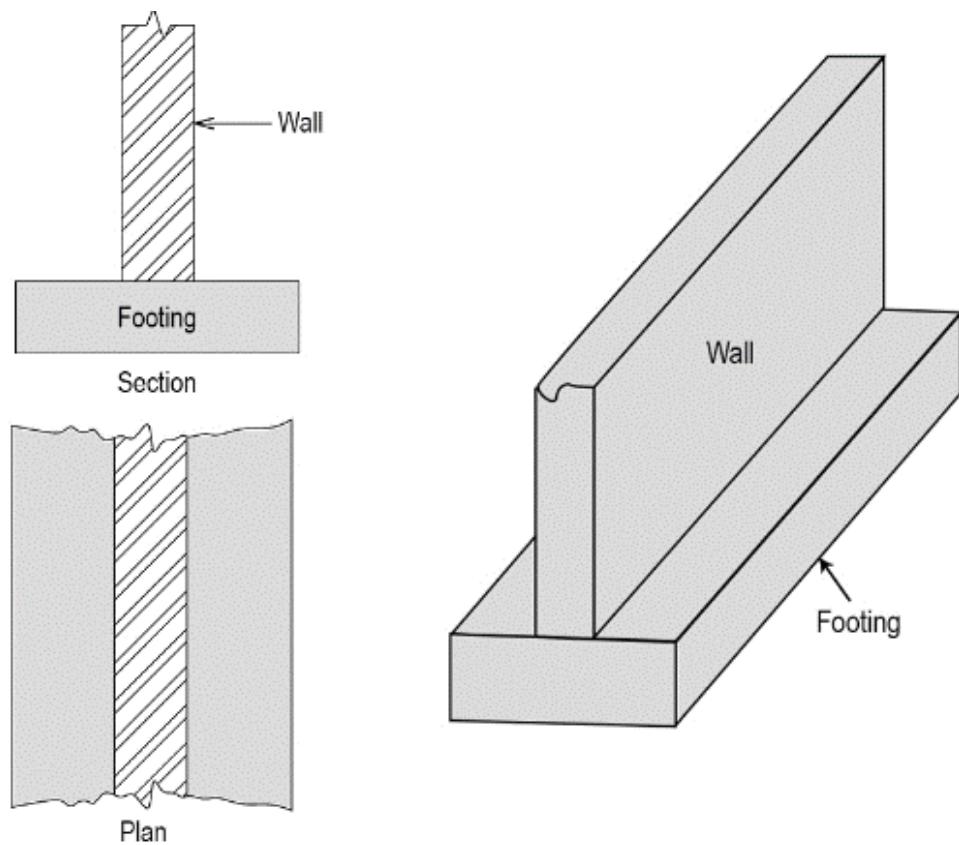

Figure 5-4 Strip footing

### 5.2.1. Equations and parameters

❖ Preliminary member sizing [5]:

$$q_n = q_a - weight_{footing} - weight_{soil} \quad (5-13)$$

$$A_{req} = \frac{P_{service}}{q_n} \quad (5-14)$$

$$q_{nu} = \frac{P_u}{A_{footing}} \quad (5-15)$$

Where:

$q_a$ ,  $q_n$  &  $q_{nu}$ : are allowable soil pressure, allowable net soil pressure and factored net pressure respectively ( $\text{kN/m}^2$ ).

$P_{service}$ : Axial force (N).

$P_u$ : Factored axial force (N).

❖ Shear capacity check [1][5]:

$$V_u = q_{nu} \times A_{tributary} \quad (5-16)$$

$$\phi V_c = 0.75 \times 0.17 \times \lambda \times \sqrt{f'_c} \times b \times d \geq V_u \quad (5-17)$$

Where:

$V_c$ : Nominal shear strength provided by concrete (N).

$\lambda$ : Modification factor to reflect the reduced mechanical properties of lightweight concrete.

$b$ : Overall length of the wall (m).

$d$ : Distance from extreme compression fiber to centroid of longitudinal tension reinforcement (mm).

$V_u$ : Factored shear force at section (N).

$A_{tributary}$ : Tributary area for one way shear ( $\text{m}^2$ ).

❖ Flexural reinforcement design [5]:

$$M_u = A_{tributary} \times \frac{L_{tributary}}{2} \quad (5-18)$$

$$A_s = \frac{M_u}{\phi \times f_y \times d} \quad (5-19)$$

$$a = \frac{A_s \times f_y}{0.85 \times f' c \times b} \quad , \quad c = \frac{a}{\beta_1} \quad (5-20)$$

$$\epsilon_t = \left( \frac{0.003}{c} \right) \times d - 0.003 \geq 0.005 \text{ Tension control} \quad (5-21)$$

$$A_s = \frac{M_u}{\phi \times f_y \times \left( d - \frac{a}{2} \right)} \geq A_{s \min} \quad (5-22)$$

$$A_{s \ min} = \text{Greater of } \left( \frac{0.0018 \times 420}{f_y}, 0.0014 \right) \times A_g \quad (5-23)$$

Where:

$A_{tributary}$ : Tributary area for flexure ( $\text{m}^2$ ).

$L_{tributary}$ : Tributary width for flexure (m).

$A_s$ : Area of the steel reinforcement ( $\text{mm}^2$ ).

a: Depth of equivalent rectangular stress block (mm).

c: Distance from extreme compression fiber to neutral axis (mm).

$\epsilon_t$ : Net tensile strain.

$A_g$ : Gross area of concrete section ( $\text{m}^2$ ).

### 5.2.2. Design by excel

An excel sheet was established following the above equations to design the strip footings. Figure 5-5 and Figure 5-6 show the excel sheet used for the design of strip footings.

Entry data

Total	0.97	19.95	2.68	7.72	9.54	40.86

### 6.3. The Comparison & Charts

- Table 6-11 shows a comprehensive inventory of the quantities of concrete and steel for both structural systems. After comparing the quantities of materials, it appears that the solid slab system requires less steel and concrete, which means that it is more efficient in terms of sustainability and economically advantageous.

Table 6-11 Comparison table between the two structural systems

Structural System	Volume of Concrete (m^3)	Volume of steel rebars (m^3)	Weight of steel rebars (ton)
Flat Slab System	447.79	7.416	58.21
Solid Slab System	415.8	5.43	42.62

- Figures 6-9 and 6-10 illustrate the ratios of the concrete and steel for the building elements

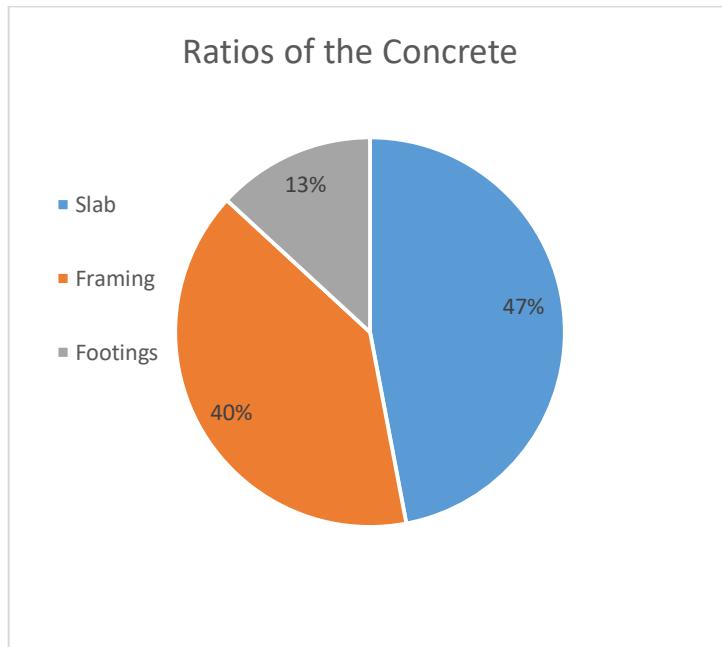

Figure 6-9 Ratios of the concrete in elements of the building

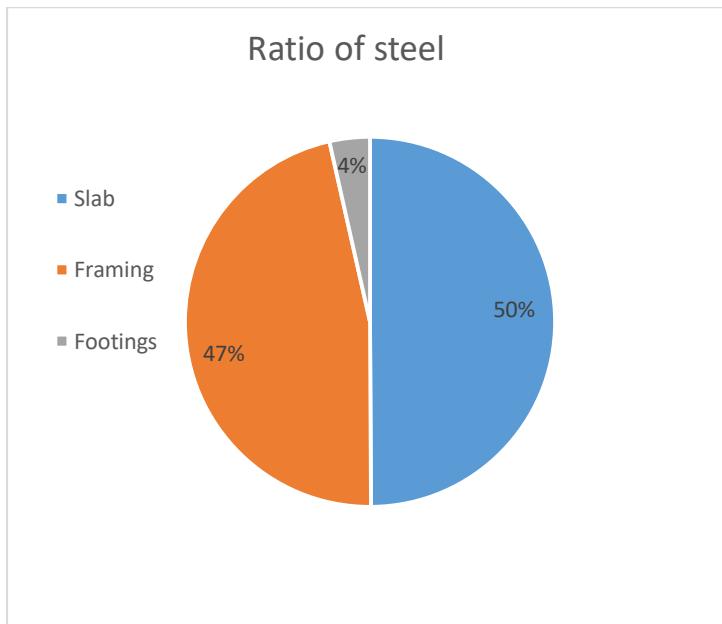

Figure 6-10 Ratios of the steel in elements of the building

## CHAPTER 7. DRAWINGS

### 7.1. General Columns-Axis Layout

- Figure 7-1 displays the general columns axis layout of the building, in which the yellow color represents columns that stops at the level of story#1, the cyan color stops at the level of story#6, and gray the columns that are to the roof of the building.

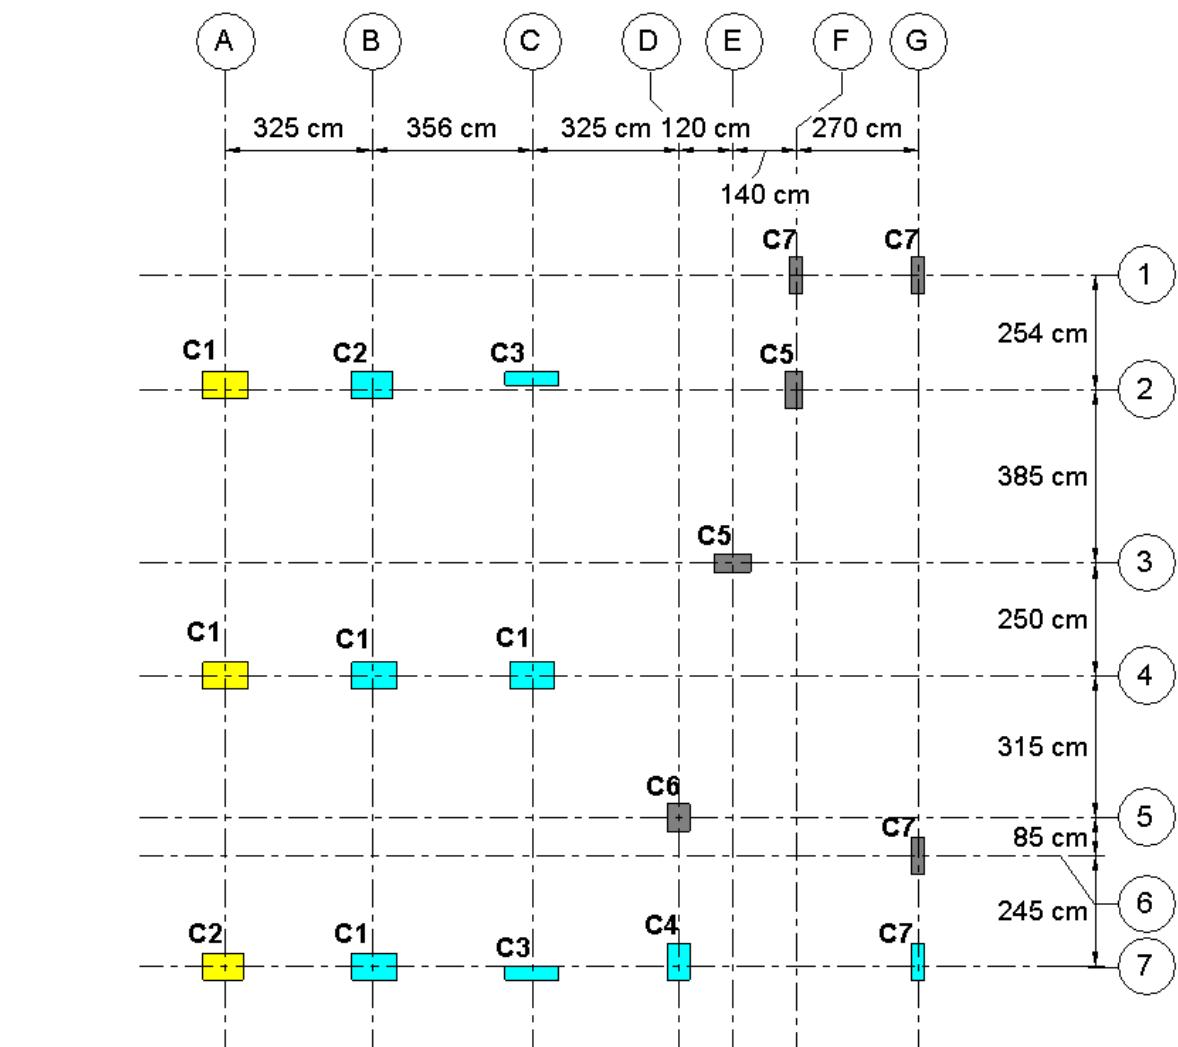

Figure 7-1 General columns-axis layout

## 7.2. Typical Detail Sectional Elevation

- Isolated concrete footing and column is shown in Figure 7-2

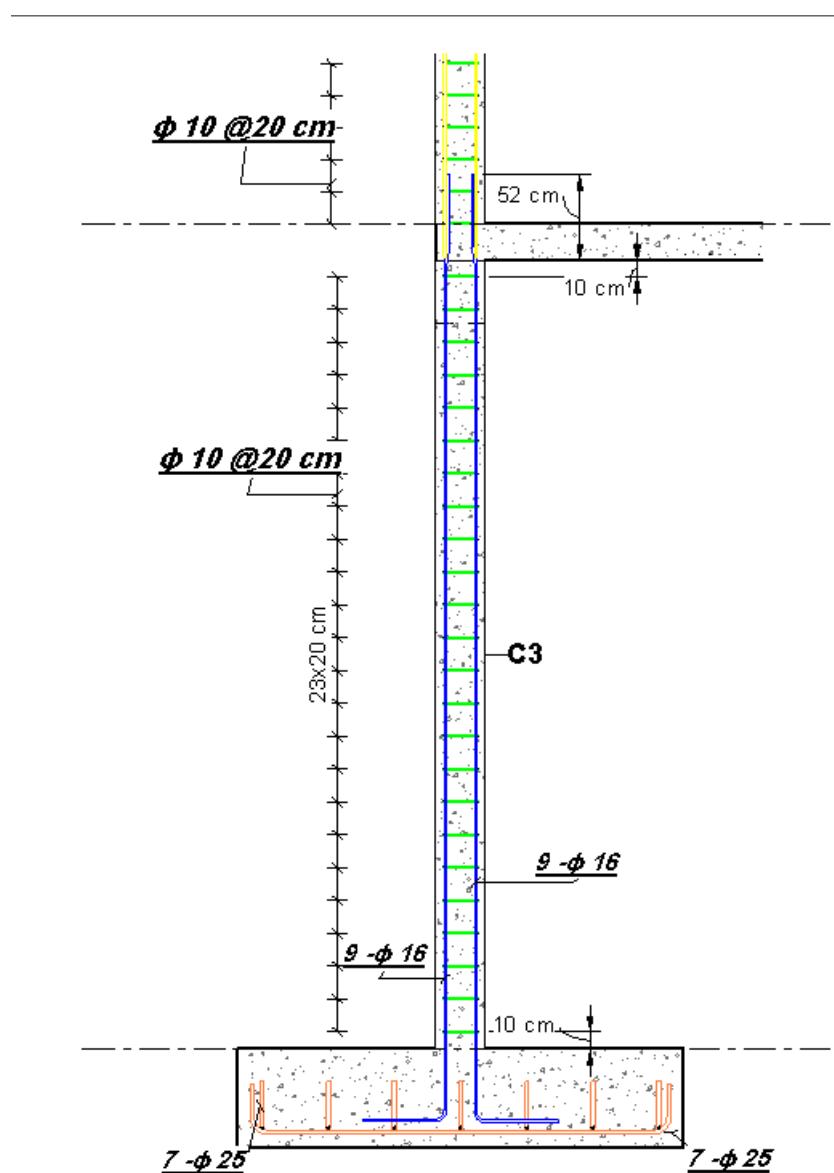

Figure 7-2 Isolated footing and column

- Typical beam detail is shown in Figure 7-3.

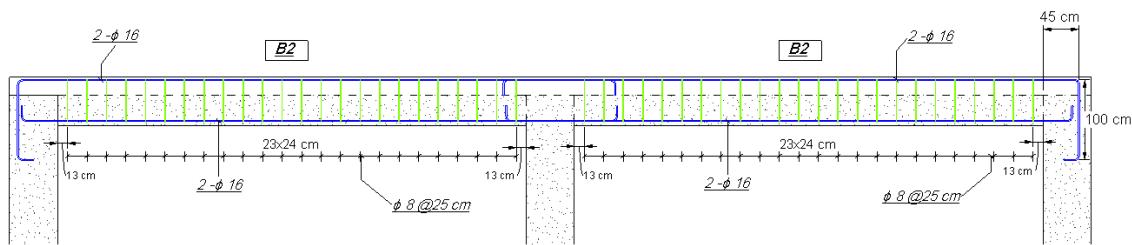

Figure 7-3 Typical beam detail

### 7.3. Columns Details

Figures 7-4, 7-5, 7-6, 7-7, 7-8, 7-9, 7-10 and 7-11 display the section's detail of the columns. The stirrups were placed according to the SBC 304 criteria to ensure confinement between rebars and to prevent any obstruction that may prevent the concrete mix from passing through column. It should be noted that in the sections C4 and C5, the stirrups were placed in the manner shown in figures 7-7 and 7-8 to avoid placing a two bars tie in the long direction of the section, which prevent more concrete mix from passing through column.

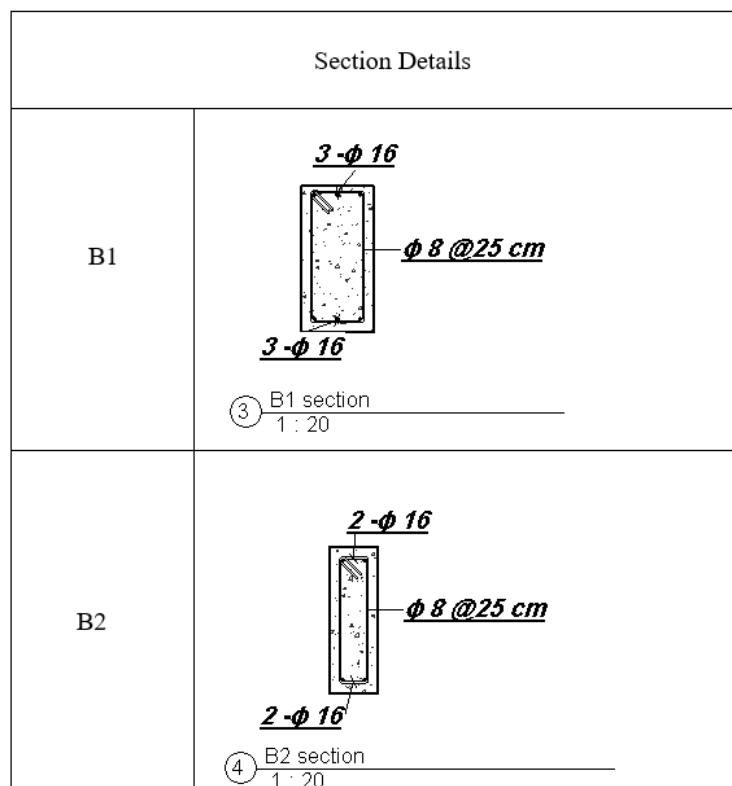

Figure 7-14 Beams section details (Flat)

## 7.5. Beams Details of Solid Slab System

- Figure 7-15 displays the beam's axis layout for the solid slab system. The beams section and reinforcement details of B1, B2, and B3 for the solid slab system is shown in Figures 7-16 and 7-17.

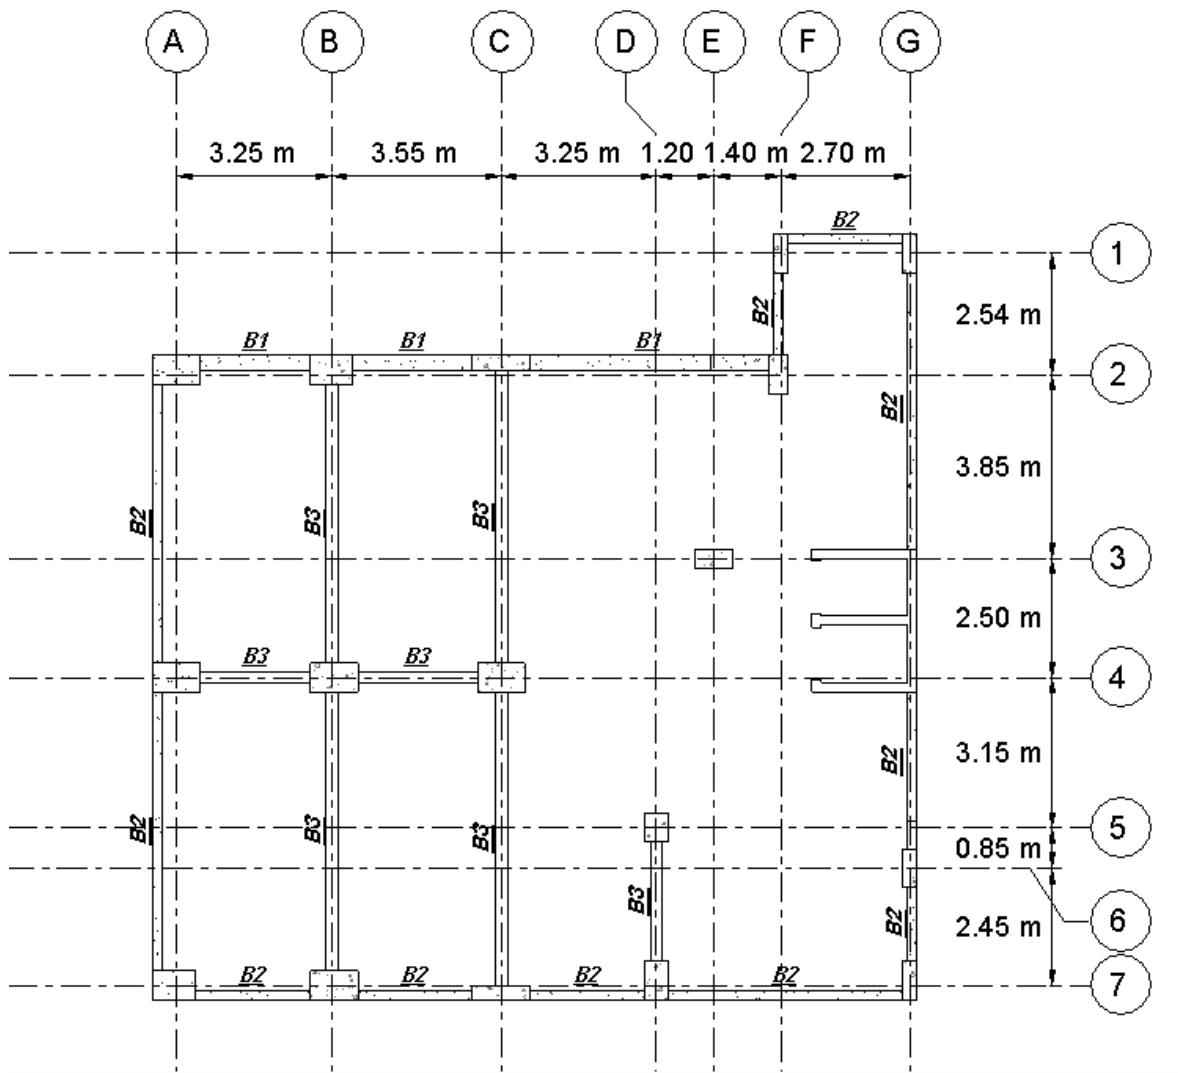

Figure 7-15 Beams-axis layout (Solid)

Beam Mark #	Dimension		Reinforcement					
	Depth (cm)	Width (cm)	Bottom Continous (B)	Top		Stirrups		
				Mid span	@ Support	Size (mm)	Spacing, mm "Ends"	Spacing, mm "Mid"
B1	60	30	3 φ 16	3 φ 16	3 φ 16	8	1 : 130 Rest 250	250
B2	60	20	3 φ 14	3 φ 14	3 φ 14	8	1 : 130 Rest 250	250
B3	40	20	2 φ 14	2 φ 14	2 φ 14	8	1 : 130 Rest 250	250

Figure 7-16 Beams reinforcement details (Solid)

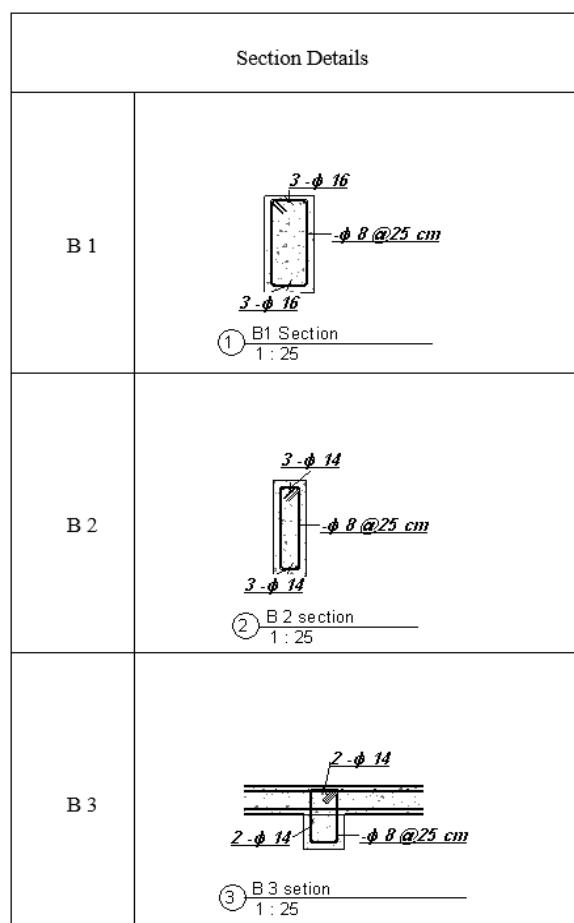

Figure 7-17 Beams section details (Solid)

## 7.6. Flat Slab Reinforcement Details

- Figure 7-18 displays the flat slab with visible reinforcement rebars that was modeled using Revit software. As detected in the design stage 4.7.1., for top reinforcement  $\Phi 14$  is selected and for bottom reinforcement  $\Phi 12$ , and additional top reinforcement  $\Phi 16$  at (E3 grid). It shall be noted that the additional cover (35mm) is made at the top to place the additional reinforcement as shown in Figure 7-20. Roof slab reinforcement details is shown in Figure 7-19.

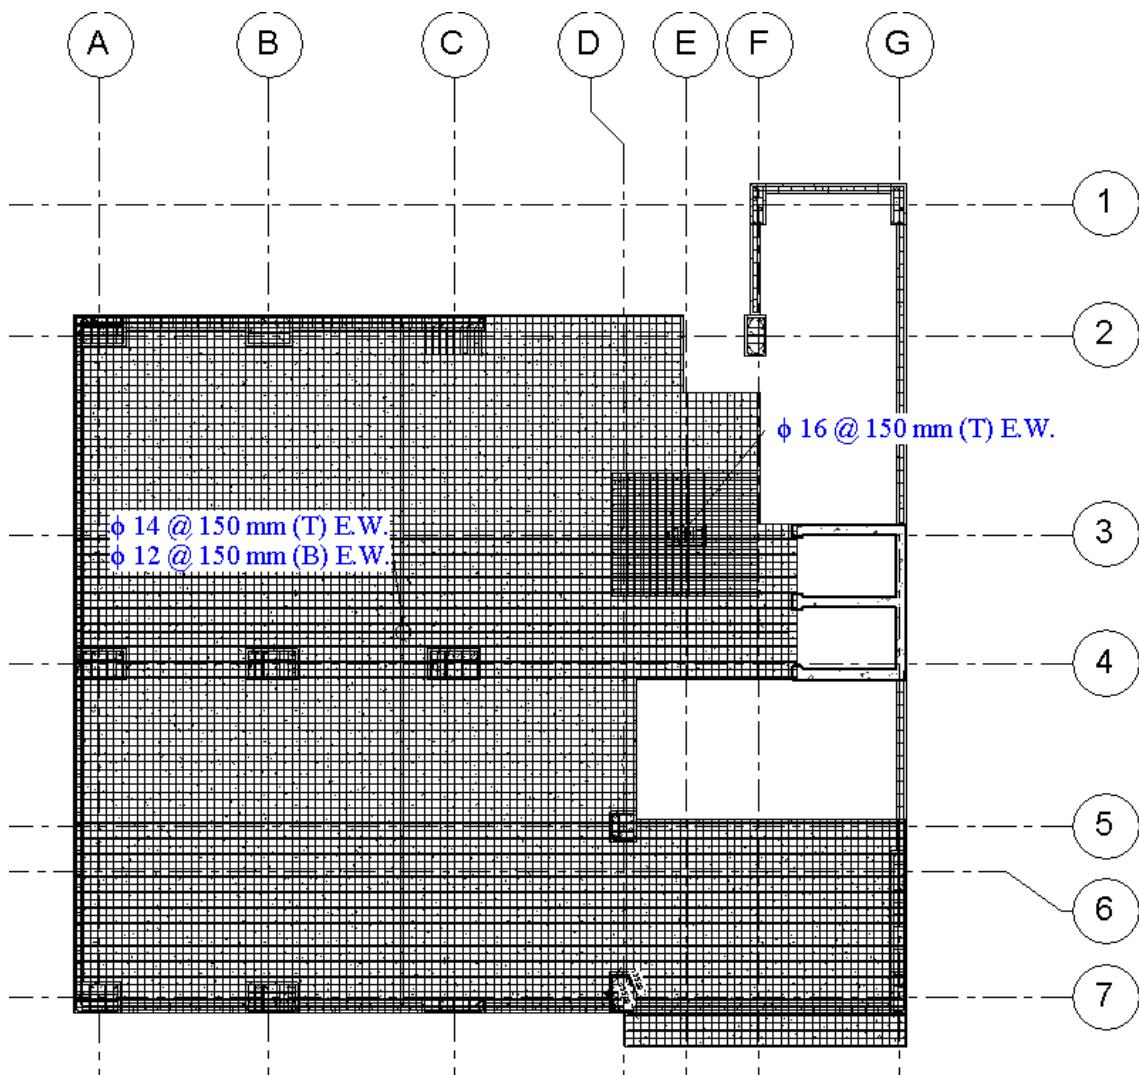

Figure 7-18 Flat slab reinforcement details

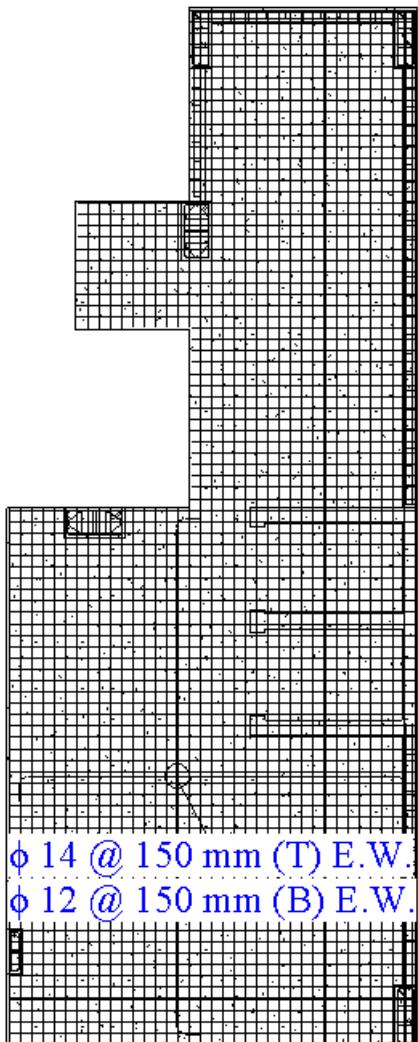

Figure 7-19 Roof slab reinforcement details

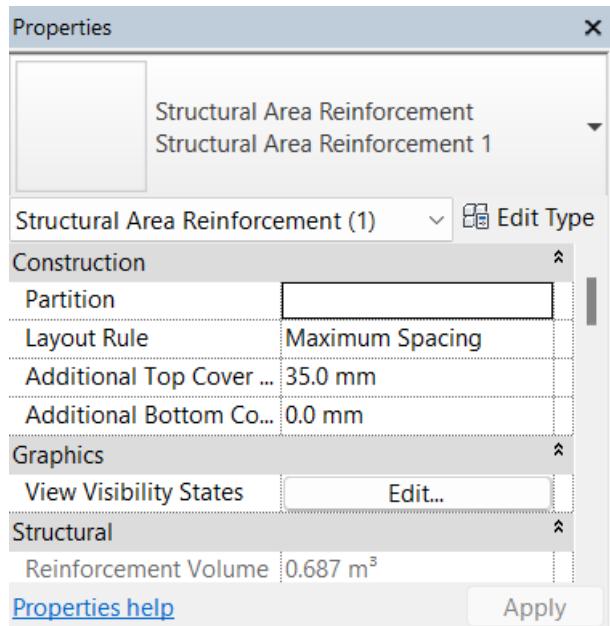

Figure 7-20 Setting slab reinforcement in Revit software

## 7.7. Solid Slab Reinforcement Details

- Figure 7-21 shows the solid slab reinforcement details, as detected in the design stage 4.7.2. for top and bottom reinforcement  $\Phi 10$  is selected. Where EW refers to Each Way and EF refers to Each Face. Roof slab reinforcement details for solid slab system is shown in Figure 7-22.

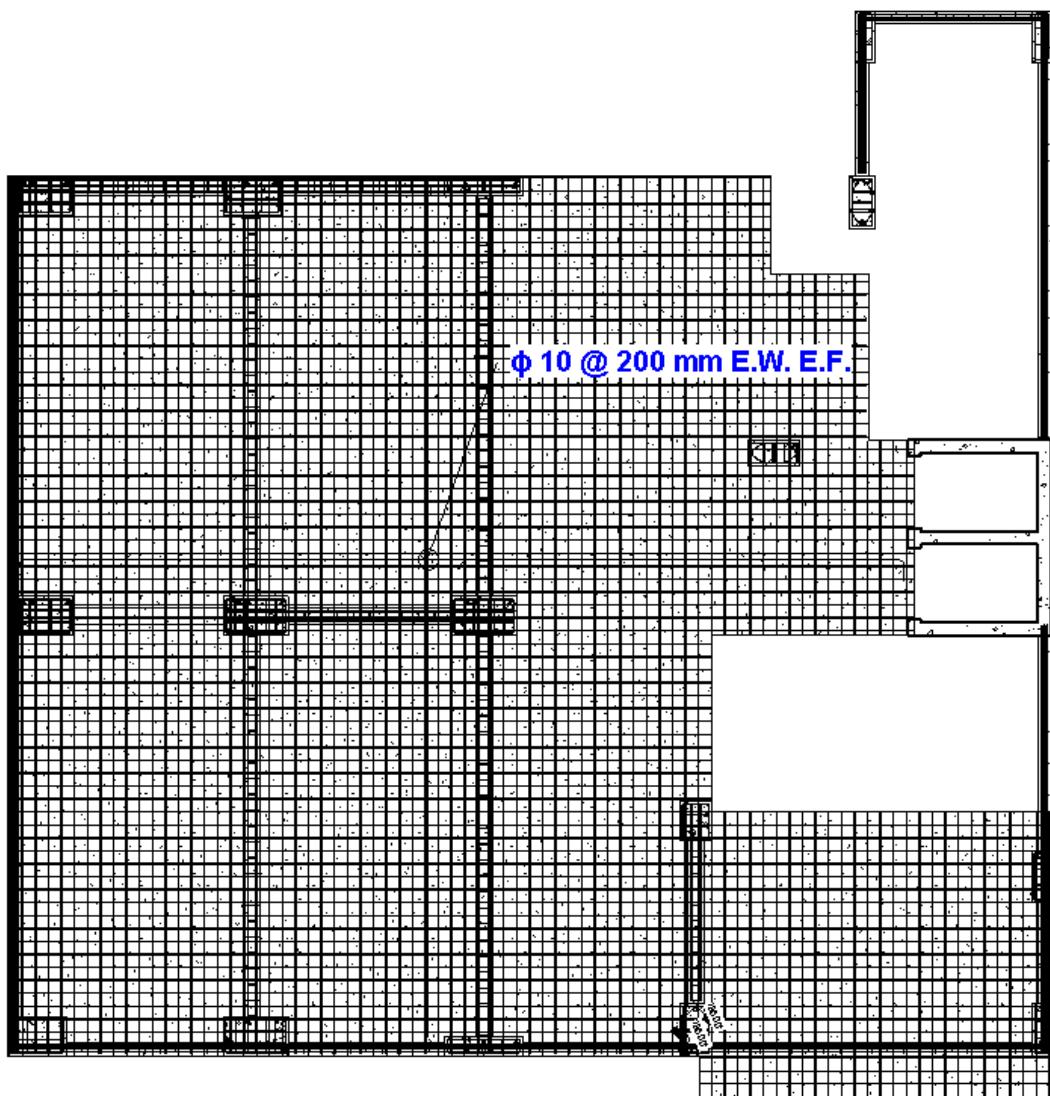

Figure 7-21 Solid slab reinforcement details

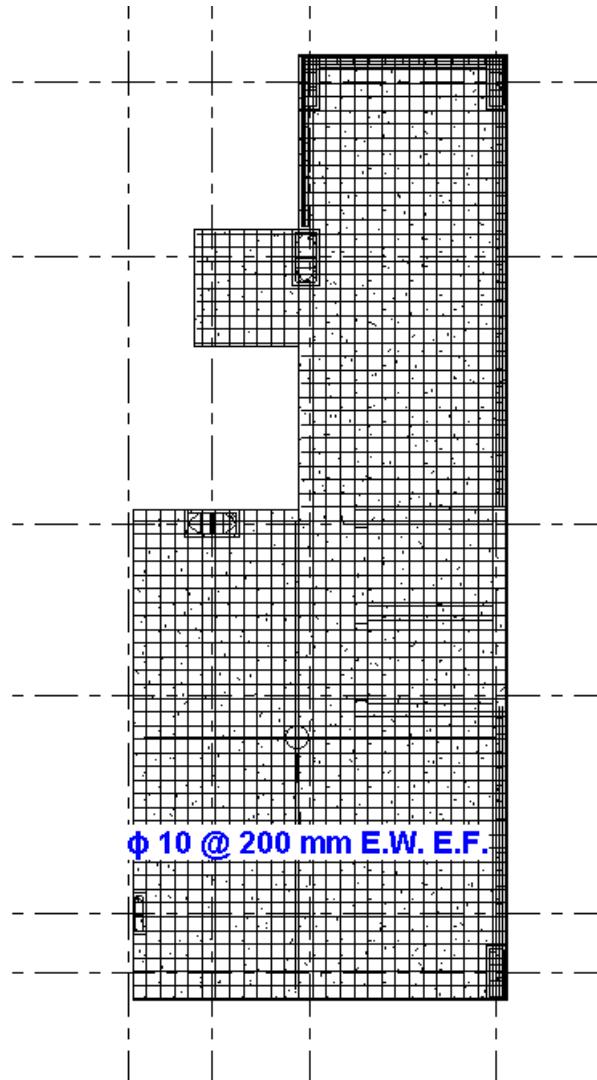

Figure 7-22 Roof slab reinforcement details (Solid)

## 7.8. Shear Wall Reinforcement Details

Figure 7-23 shows the shear wall sample reinforcement detailing, which include the longitudinal or flexural reinforcement in addition to the horizontal or shear reinforcement.

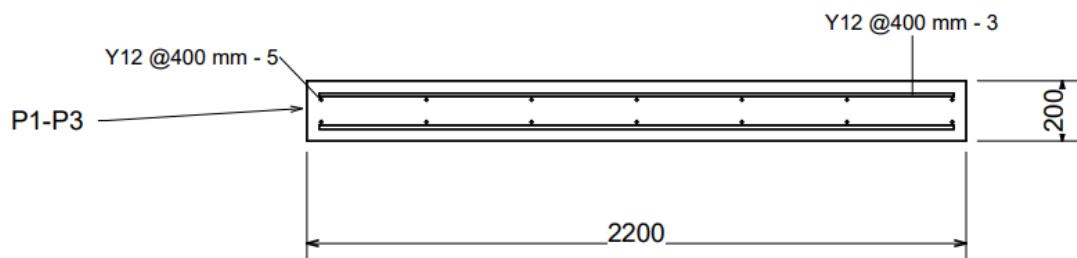

Figure 7-23 Shear wall reinforcement

## 7.9. Strip Footing Reinforcement Details

Figure 7-24 shows the strip footing reinforcement detailing.

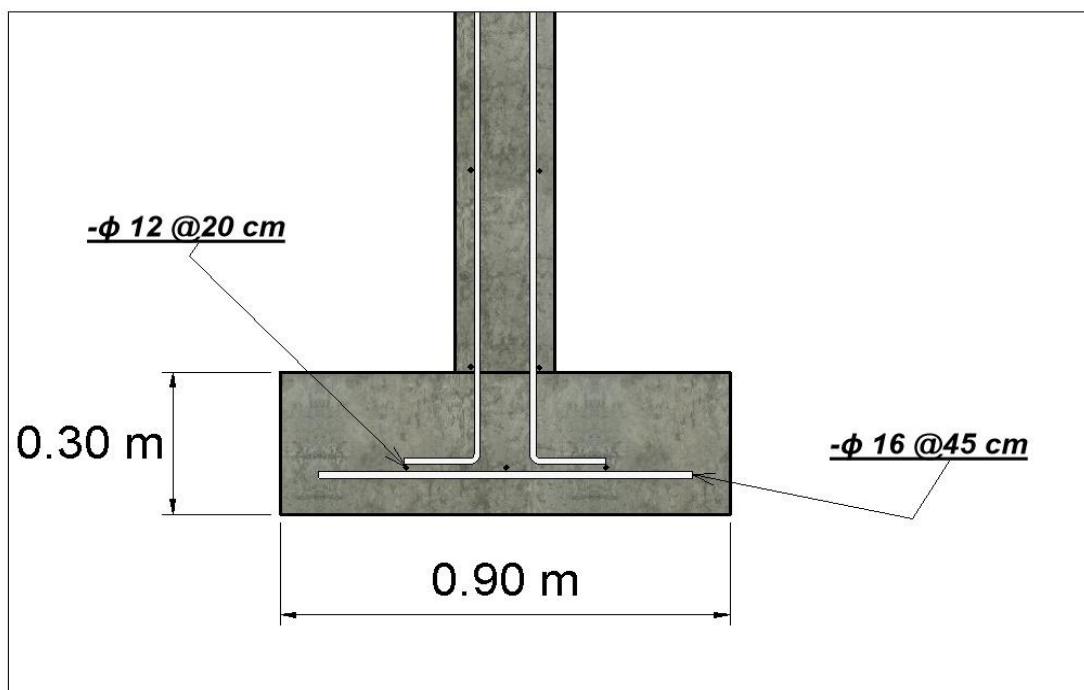

Figure 7-24 Strip footing reinforcement

## CHAPTER 8. CONCLUSION

To summarize, in SDP I, the primary focus was on designing the building structure to withstand gravity loads. A comparison was made between the flat slab and solid slab systems in terms of material quantities and structural integrity. The structural elements considered in SDP1 included slabs, beams, columns, and isolated footings for columns. The findings were as follows:

1. The flat slab system required  $447.79 \text{ m}^3$  of concrete and 58.21 tons of reinforcement steel.
2. The solid slab system required  $415.8 \text{ m}^3$  of concrete and 42.62 tons of reinforcement steel.

Based on these findings, it is evident that the solid slab system is more cost-effective and sufficient.

Moving on to SDP II, wind and seismic loads were manually determined and applied to the building structure using ETABS software. The chosen lateral resisting system was shear walls. The placement of shear walls was carefully done to avoid torsion on the building, resulting in an average eccentricity of 3.7% on the x-axis and 6.7% on the y-axis with respect to the center of mass and rigidity. The design of shear walls was carried out using the Uniform Reinforcing approach in ETABS. The foundations for the walls were manually designed, considering the axial loads from the walls. Finally, all the structural elements were transferred to Revit software for reinforcement and detailed drawings.

## CHAPTER 9. APPENDICES

### Appendix A (Maps and Design tables for wind loads)

#### *9.1.1. A-1 Risk category of buildings and other structure*

RISK CATEGORY	NATURE OF OCCUPANCY
I	Buildings and other structures that represent a low hazard to human life in the event of failure, including but not limited to: <ul style="list-style-type: none"> <li>• Agricultural facilities.</li> <li>• Certain temporary facilities.</li> <li>• Minor storage facilities.</li> </ul>
II	Buildings and other structures except those listed in Risk Categories I, III and IV.
III	Buildings and other structures that represent a substantial hazard to human life in the event of failure, including but not limited to: <ul style="list-style-type: none"> <li>• Buildings and other structures whose primary occupancy is public assembly with an occupant load greater than 300.</li> <li>• Buildings and other structures containing Group E occupancies with an occupant load greater than 250.</li> <li>• Buildings and other structures containing educational occupancies for students above the 12<sup>th</sup> grade with an occupant load greater than 500.</li> <li>• Group I-2 occupancies with an occupant load of 50 or more resident care recipients but not having surgery or emergency treatment facilities.</li> <li>• Group I-3 occupancies.</li> <li>• Any other occupancy with an occupant load greater than 5,000.<sup>a</sup></li> <li>• Power-generating stations, water treatment facilities for potable water, wastewater treatment facilities and other public utility facilities not included in Risk Category IV.</li> <li>• Buildings and other structures not included in Risk Category IV containing quantities of toxic or explosive materials that:               <ul style="list-style-type: none"> <li>Exceed maximum allowable quantities per control area as given in Table 307.1(1) or 307.1(2) of SBC 201 or per outdoor control area in accordance with the <i>SBC 801</i>; and</li> <li>Are sufficient to pose a threat to the public if released.<sup>b</sup></li> </ul> </li> </ul>
IV	Buildings and other structures designated as essential facilities, including but not limited to: <ul style="list-style-type: none"> <li>• Group I-2 occupancies having surgery or emergency treatment facilities.</li> <li>• Fire, rescue, ambulance and police stations and emergency vehicle garages.</li> <li>• Designated earthquake, hurricane or other emergency shelters.</li> <li>• Designated emergency preparedness, communications and operations centers and other facilities required for emergency response.</li> <li>• Power-generating stations and other public utility facilities required as emergency backup facilities for Risk Category IV structures.</li> <li>• Buildings and other structures containing quantities of highly toxic materials that:               <ul style="list-style-type: none"> <li>Exceed maximum allowable quantities per control area as given in Table 307.1(2) of SBC 201 or per outdoor control area in accordance with the <i>SBC 801</i>; and</li> <li>Are sufficient to pose a threat to the public if released<sup>b</sup>.</li> </ul> </li> <li>• Aviation control towers, air traffic control centers and emergency aircraft hangars.</li> <li>• Buildings and other structures having critical national defense functions.</li> <li>• Water storage facilities and pump structures required to maintain water pressure for fire suppression.</li> </ul>

Figure 9-1 Risk category of buildings and other structures

### 9.1.2. A-2 Ultimate wind speed map for risk category II

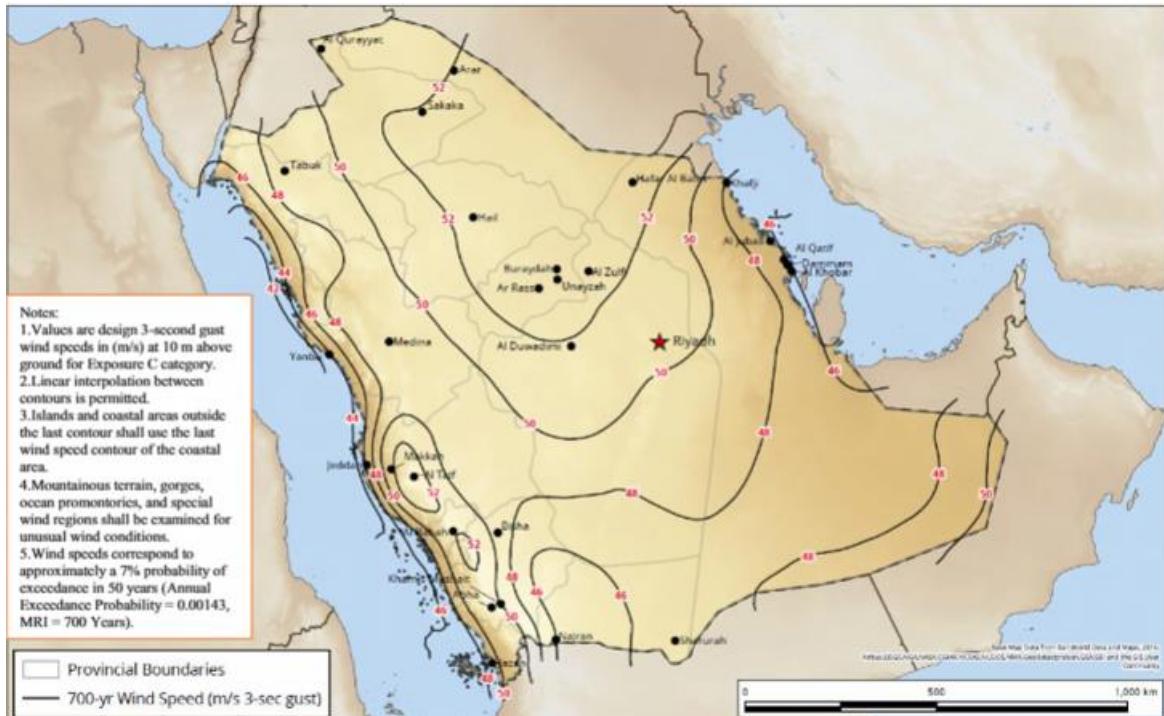

Figure 9-2 Ultimate wind speed category for risk category II

### 9.1.3. A-3 Wind directionality factor, $K_d$

Structure Type	Directionality Factor $K_d^*$
Buildings	
Main Wind Force Resisting System	0.85
Components and Cladding	0.85
Arched Roofs	0.85
Chimneys, Tanks, and Similar Structures	
Square	0.90
Hexagonal	0.95
Round	0.95
Solid Freestanding Walls and Solid Freestanding and Attached Signs	0.85
Open Signs and Lattice Framework	0.85
Trussed Towers	
Triangular, square, rectangular	0.85
All other cross sections	0.95

Figure 9-3 Table of wind directionality factor,  $K_d$

#### **9.1.4. A-4 Exposure category**

- (a) **Surface Roughness B:** Urban and suburban areas, wooded areas, or other terrain with numerous closely spaced obstructions having the size of single-family dwellings or larger.
- (b) **Surface Roughness C:** Open terrain with scattered obstructions having heights generally less than 10 m. This category includes flat open country and grasslands.
- (c) **Surface Roughness D:** Flat, unobstructed areas and water surfaces. This category includes smooth mud flats and salt flats.

##### **26.7.4 Exposure Categories.**

###### **26.7.4.1 Exposure B:**

- (a) For buildings with a mean roof height of less than or equal to 9 m, Exposure B shall apply where the ground surface roughness, as defined by Surface Roughness B, prevails in the upwind direction for a distance greater than 450 m.
- (b) For buildings with a mean roof height greater than 9 m, Exposure B shall apply where Surface Roughness B prevails in the upwind direction for a distance greater than 780 m or 20 times the height of the building, whichever is greater.

###### **26.7.4.2 Exposure C:**

- (a) Exposure C shall apply for all cases where Exposures B or D do not apply.

###### **26.7.4.3 Exposure D:**

- (a) Exposure D shall apply where the ground surface roughness, as defined by Surface

Figure 9-4 Exposure category section from SBC 301

### 9.1.5. A-5 Topographic factor, $K_{zt}$

#### 26.8 —Topographic effects

##### 26.8.1 Wind Speed-Up over Hills, Ridges, and Escarpments.

Wind speed-up effects at isolated hills, ridges, and escarpments constituting abrupt changes in the general topography, located in any exposure category, shall be included in the determination of the wind loads when buildings and other site conditions and locations of structures meet all of the following conditions:

1. The hill, ridge, or escarpment is isolated and unobstructed upwind by other similar topographic features of comparable height for 100 times the height of the topographic feature ( $100H$ ) or 3 km, whichever is less. This distance shall be measured horizontally from the point at which the height  $H$  of the hill, ridge, or escarpment is determined.
2. The hill, ridge, or escarpment protrudes above the height of upwind terrain features within a 3 km radius in any quadrant by a factor of two or more.
3. The structure is located as shown in Figure 26-3 in the upper one-half of a hill or ridge or near the crest of an escarpment.
4.  $H/L_h \geq 0.2$ .
5.  $H$  is greater than or equal to 5 m for Exposure C and D and 18 m for Exposure B.

##### 26.8.2 Topographic Factor.

26.8.2.1 The wind speed-up effect shall be included in the calculation of design wind loads by using the factor  $K_{zt}$

$$K_{zt} = (1 + K_1 K_2 K_3)^2 \quad (26-1)$$

where  $K_1$ ,  $K_2$ , and  $K_3$  are given in Figure 26-3.

26.8.2.2 If site conditions and locations of buildings and other structures do not meet all the conditions specified in Section 26.8.1 then  $K_{zt} = 1.0$ .

Figure 9-5 Topographic factor section from SBC 301

### 9.1.6. A-6 Gust effect factor, $G$

#### 26.9 —Gust-effects

26.9.1 Gust-Effect Factor. The gust-effect factor for a rigid building or other structure is permitted to be taken as 0.85.

Figure 9-6 Gust effect factor section from SBC 301

### **9.1.7. A-7 Enclosure classification**

(such as solid freestanding walls and solid freestanding signs, chimneys, tanks, open signs, lattice frameworks, and trussed towers) as specified in **CHAPTER 29**;

4. Wind Tunnel Procedure for all buildings and all other structures as specified in **CHAPTER 31**.

**26.1.2.2 Components and Cladding.** Wind loads on components and cladding on all buildings and other structures shall be designed using one of the following procedures:

1. Analytical Procedures provided in Parts 1 through 6, as appropriate, of **CHAPTER 30**;

SBC 301-CR-18

232

The version is free for Public Access only  
CHAPTER 26—WIND LOADS: GENERAL REQUIREMENTS

balance of the building envelope (walls and roof) by more than 10 percent.

2. The total area of openings in a wall that receives positive external pressure exceeds  $0.4 \text{ m}^2$  or 1 percent of the area of that wall, whichever is smaller, and the percentage of openings in the balance of the building envelope does not exceed 20 percent.

These conditions are expressed by the following

**BUILDING, OPEN**—A building having each wall at least 80 percent open. This condition is expressed for each wall by the equation  $A_o \geq 0.8 A_g$ ; where,  $A_o$  = total area of openings in a wall that receives positive external pressure, in  $\text{m}^2$ ;  $A_g$  = the gross area of that wall in which  $A_o$  is identified, in  $\text{m}^2$ .

**BUILDING, PARTIALLY ENCLOSED**

—A building that complies with both of the following conditions:

- The total area of openings in a wall that receives positive external pressure exceeds the sum of the areas of openings in the

Figure 9-7 Enclosure classification definitions

#### **9.1.8. A-8 Internal pressure coefficient, $GC_{pi}$**

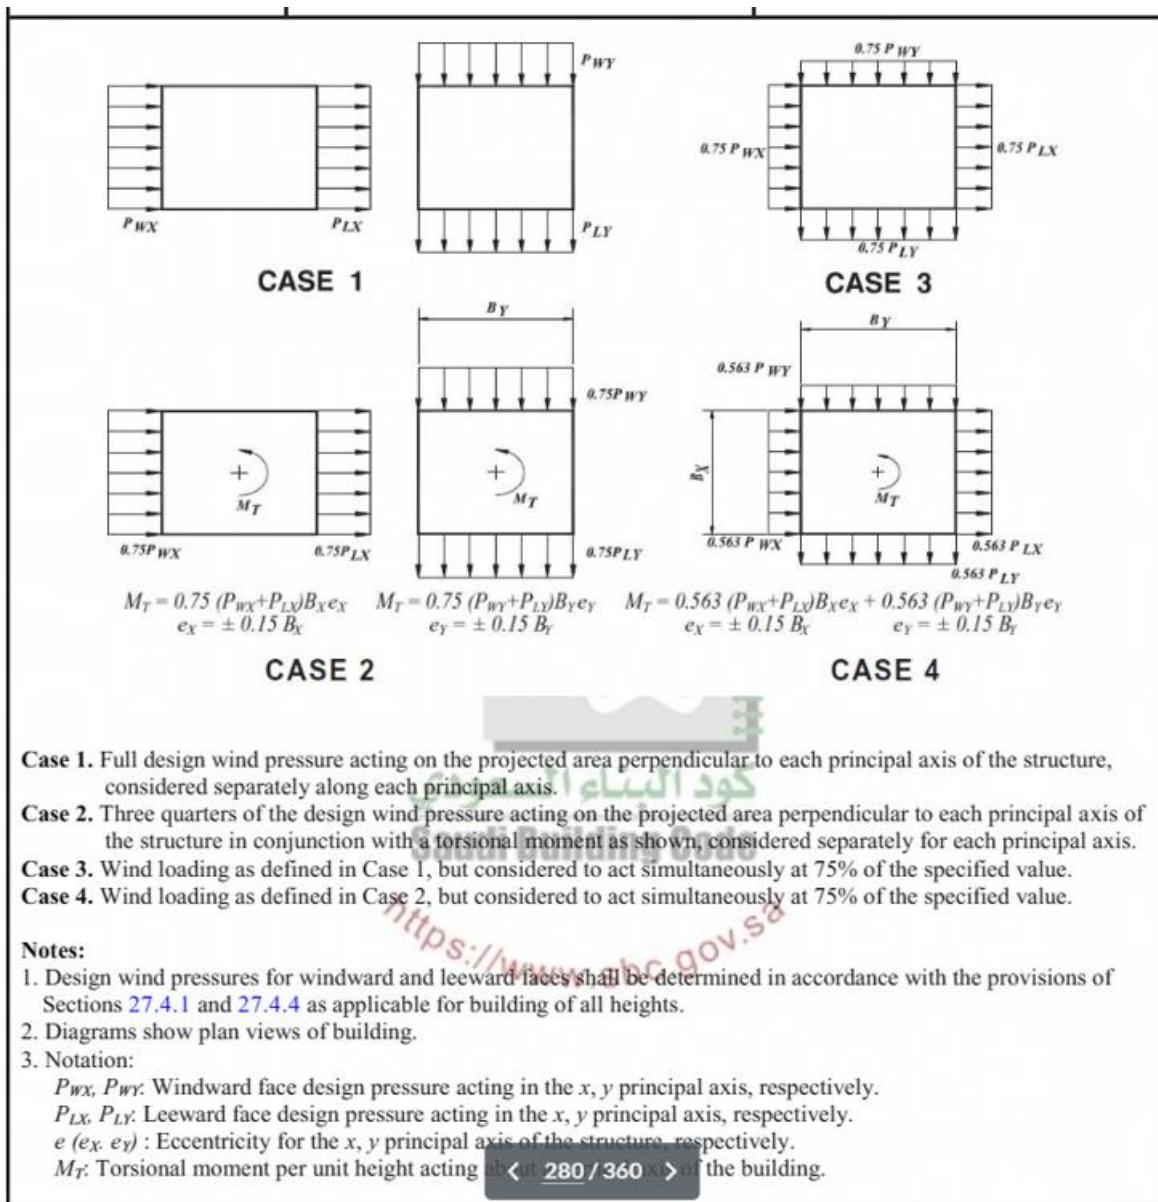

Enclosure Classification	Internal Pressure Coefficient ( $GC_{pi}$ )
Open Buildings	0.00
Partially Enclosed Buildings	+0.55 - 0.55
Enclosed Buildings	+0.18 - 0.18

#### Notes:

1. Plus and minus signs signify pressures acting toward and away from the internal surfaces, respectively.
  2. Values of  $(GC_{pl})$  shall be used with  $q_z$  or  $q_h$  as specified.
  3. Two cases shall be considered to determine the critical load requirements for the appropriate condition:
    - (i) a positive value of  $(GC_{pl})$  applied to all internal surfaces
    - (ii) a negative value of  $(GC_{pl})$  applied to all internal surfaces

Figure 9-8 Table of internal pressure coefficient

### 9.1.9. A-9 Design wind load cases

- Case 1.** Full design wind pressure acting on the projected area perpendicular to each principal axis of the structure, considered separately along each principal axis.
- Case 2.** Three quarters of the design wind pressure acting on the projected area perpendicular to each principal axis of the structure in conjunction with a torsional moment as shown, considered separately for each principal axis.
- Case 3.** Wind loading as defined in Case 1, but considered to act simultaneously at 75% of the specified value.
- Case 4.** Wind loading as defined in Case 2, but considered to act simultaneously at 75% of the specified value.

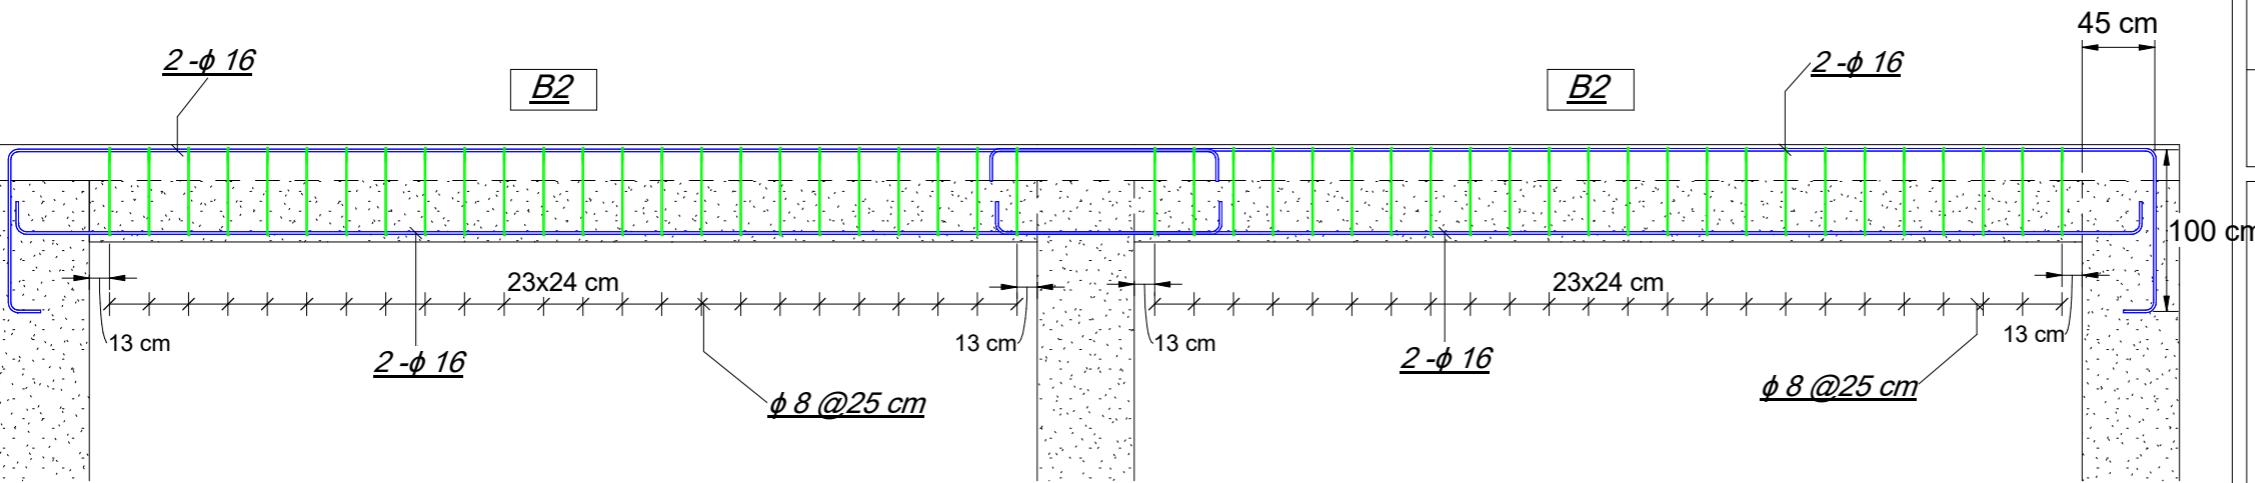

**Notes:**

- Design wind pressures for windward and leeward faces shall be determined in accordance with the provisions of Sections 27.4.1 and 27.4.4 as applicable for building of all heights.
- Diagrams show plan views of building.
- Notation:
  - $P_{WX}, P_{WY}$ : Windward face design pressure acting in the  $x, y$  principal axis, respectively.
  - $P_{LY}, P_{LY}$ : Leeward face design pressure acting in the  $x, y$  principal axis, respectively.
  - $e (e_X, e_Y)$ : Eccentricity for the  $x, y$  principal axis of the structure, respectively.
  - $M_T$ : Torsional moment per unit height acting about the building.
